Air Ministry METEOROLOGICAL OFFICE

OBSERVATORIES' YEAR BOOK

Comprising the meteorological and geophysical results obtained from autographic records and eye observations at the observatories at Lerwick, Aberdeen, Esklalemuir, Valentia, and Kew, and the results of soundings of the upper atmosphere by means of registering balloons.

Published by the authority of the METEOROLOGICAL COMMITTEE

PREFACE.

From 1908 to 1921, the serial statistical publications of the Meteorological Office were grouped together as though they were parts of one comprehensive book. This book, which was entitled "The British Meteorological and Magnetic Year Book," consisted of:—

Part	Ι	• •	• •			The Weekly Weather Report.
Part	II	• •		• •		The Monthly Weather Report.
Part	III,	Section	Ι	••	••.	Daily Readings at Meteorological stations of the First and Second Orders.
		Section	II .	••	.••	Geophysical Journal, Daily Values of Meteorological and Geophysical Ele- ments.
Part	IV,	Section	Ι	••	••	Hourly Values from Autographic Records, Meteorological Section.
		Section	II	• • ,	• •	Hourly Values from Autographic Records, Geophysical Section.
Part	V	• •	• •	• •	• •	Réseau Mondial.

The data for the year 1922 and subsequent years are found in the following publications:—

New Publication from 1922.		Corresponding parts of the British Meteorological and Magnetic Year Book until the end of 1921.					
The Weekly Weather Report The Monthly Weather Report	• •	••	Part I Part II.				
The Observatories' Year Book		. • •	Part III, Section II. Part IV, Section I.*				
The Réseau Mondial		• •	Part IV, Section II. Part V.				

It will be noticed that Part III, Section I, of the old publication is not included in the new issues. This part contained "Daily Readings at Meteorological Stations of the First and Second Orders," and it has been decided that as the Observatories' Year Book contains daily values of the meteorological elements for the principal first order stations and the Daily Weather Report contains daily values for these and about 40 other stations, it is not necessary to revive the issue of this section, which ceased with the data for 1921.

The present volume is the fourteenth issue of the Observatories' Year Book. It contains geophysical data for Lerwick, Eskdalemuir, Valentia and Kew, meteorological data for Aberdeen, Eskdalemuir, Valentia and Kew, and in addition an aerological section giving the results of soundings of the upper atmosphere by means of registering balloons.

The table of mean annual values of magnetic data for observatories of the globe has been contributed by the Astronomer Royal. It will be found at the end of the Eskdalemuir section.

*Part IV, Section I, Hourly Values from Autographic Records, Meteorological Section, was discontinued after the data for 1913 had been published. The hourly values for the years 1914 to 1921 are, however, available in manuscript.

NORMAL VALUES AND MONTHLY SUMMARIES.

Monthly and annual normals of pressure, dry bulb temperature, and rainfall for each hour of the day and for the period of 45 years, 1871–1915, are published for the observatories, Aberdeen, Valentia, Kew and Falmouth in *Hourly Values from Autographic Records*, 1917 (Part IV of the British Meteorological and Magnetic Year Book, 1917), and in previous volumes of that series. Corresponding normals of wind-speed and sunshine are published there for the same observatories and for the period of 35 years, 1881–1915, while corresponding normals of relative humidity are also published there for the period of 30 years, 1886–1915. For Eskdalemuir the same publication gives hourly averages for the months and for the year, referred to the period 1911–1915.

It should be noted, however, that the normal hourly values in the case of wind, rainfall and sunshine refer to periods of 60 minutes centred at exact hours G.M.T., and are therefore not directly comparable with the values printed in this volume which refer to periods of 60 minutes ended at exact hours G.M.T.

Summaries giving additional mean values and frequencies of occurrence of various meteorological phenomena will be found for all the observatories in *The Monthly Weather Report* and its Annual Summary. The latter also contains special summaries of the tabulations of the anemographs.

Monthly normal values of maximum, minimum and mean temperature, rainfall and sunshine for the period 1881-1915 are published in the Book of Normals, Section I, for Aberdeen, Valentia, Kew and Falmouth. Section IV of the same publication gives information regarding the range of variation of temperature and rainfall at the same observatories, and monthly frequencies of the normal numbers of days of hail, thunder, snow, snow-lying and ground frost. Section VI of the Book of Normals gives tables and isopleth diagrams showing the normal diurnal and seasonal variation of relative humidity at all the observatories for which data of relative humidity are included in this volume.

Monthly average values of maximum, minimum and mean temperature for 1906—1935 in the cases of Aberdeen, Valentia and Kew, and for the period 1910–1935 in the case of Eskdalemuir are published in Averages of Temperature for the British Isles.

Averages of total monthly duration and daily mean duration of bright sunshine for similar periods are published in Averages of Bright Sunshine for the British Isles.

[†] The site of the rain-gauge was altered on 1st June 1928 to a height of 11.4 metres and on 1st April 1933 to a height of 24.1 metres.

^{*}The normals of hourly values of sunshine for Aberdeen for all months except February are incorrect, owing to an error in computation. The published values except February, should be increased by one-third.

GENERAL INTRODUCTION TO THE METEOROLOGICAL TABLES.

The elements dealt with in the following meteorological tables for the Observatories at Aberdeen, Eskdalemuir, Valentia and Kew are:—barometric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, minimum night temperature on the grass, temperature in the ground, cloud, visibility and weather, and in some cases solar radiation and level of underground water.

The positions of the Observatories and the heights of the sites are given on p.10.

Notes on the Instruments and Tabulation of the Records.

A detailed description of the barograph, thermograph, and Beckley rain-gauge used for obtaining the records of pressure, temperature, humidity, and rainfall is given in the Reports of the Meteorological Office for the years 1867 and 1869; for a description of other instruments in use reference may be made to the Meteorological Observer's Handbook and to the article on Meteorological Instruments in the Dictionary of Applied Physics, Vol. III. The following notes are supplementary and are given partly for reference and partly as containing information necessary for the interpretation of the tables.

Barometer.—The record of barometric pressure is obtained photographically from a mercurial barometer.

By means of a source of light, a condenser and an objective arranged as in the ordinary optical lantern, an image of the space above the mercury in the tube, reduced to very small width by means of a diaphragm, is projected upside down upon a sheet of photographic ("bromide") paper carried upon a cylinder which is rotated by means of clockwork and makes one revolution about its vertical axis in rather more than 48 hours. The image is in the form of a vertical line of light, the upper edge of which is defined by the position of the mercury in the barometer tube, while the lower edge is defined by a plate actuated by a zinc rod. The purpose of the zinc rod is to provide an automatic compensation for temperature changes, the arrangement being such that any shortening of the line of light due to a rise of temperature and consequent expansion of mercury in the tube is balanced by an equal lengthening due to movement of the plate carried on the zinc rod.

The barogram is, therefore, a continuous photograph of a narrow illuminated vertical line and appears as a horizontal ribbon, the depth of which is constantly varying with the rise or fall of the mercury in the tube of the barometer.

A time-scale is recorded upon the barogram by means of a shutter actuated by the clock. This shutter cuts off the light for the space of four minutes every two hours, thus producing interruptions which appear on the record as narrow white spaces corresponding with intervals of four minutes centred at the half hours 1h 30m, 3h 30m, etc. Until 1918 these time-breaks occurred at the even hours, 2h, 4h, 6h, etc., but it was found that when the edge of the record was not critically sharp owing to various causes, a systematic error was introduced when measuring the records, whereby the values at the even hours were slightly in excess of those at the odd hours where no time-break existed. From 1918 onwards the clock was so arranged that the time-breaks should occur half an hour before the even hours; by this means both even and odd hour-values are measured at points on the trace which are unaffected by any systematic difference.

Control readings of a standard barometer are taken three times a day by different observers. The control readings are first corrected for index error, temperature and gravity, and then compared with the corresponding readings of the barogram. The differences between the control readings and the corresponding tabulated values

are then found and a correction derived therefrom is applied to all the tabulated values. This correction, known as the "residual correction," is so applied as to run smoothly throughout the whole length of each record—a period of 48 hours—and alterations in the amount of the correction occur, where necessary, in steps not exceeding o-r millibar.*

 $\sqrt{0}$

The scale value of the barograms is found from a comparison of a series of such standard and curve readings. The indications of a curve are converted into numerical values by measuring the ordinates with a tabulating instrument, graduated according to the ascertained scale value.

Thermometers.—The air temperature and humidity data at each Observatory are derived from records obtained photographically from two mercurial thermometers. One thermometer is used as a dry bulb and the other as a wet bulb thermometer.

Each thermometer has a large cylindrical bulb four inches long and a very long stem. The latter is bent twice at right angles to enable the bulb to be exposed outside the building in a louvred screen attached to the north wall of the Observatory.† The column of mercury in the vertical portion of the stem inside the building is broken at a convenient point by a small air space which moves up or down the stem with rise or fall of temperature. The record is obtained by passing a reflected beam of light through the air space and photographing its image upon a moving sheet of "bromide" paper in the same manner as described in the case of the barometer. A base line is traced on the paper by a pencil of light passing through a small aperture in the brass frame carrying the recording thermometer. The time-scale is automatically recorded upon the curves, a time-break occurring half an hour before each even hour.

Two large standard thermometers with very open scales graduated in degrees absolute and having bulbs similar to those of the thermograph are mounted in the screen side by side and close to the thermograph bulbs. One of the thermometers is arranged as a dry bulb, the other as a wet bulb. Control readings of these thermometers are made three times a day for comparison with the corresponding readings obtained from the thermograms.

The scale-value of the curves is found by a comparison of the readings of the standard thermometers, corrected for any errors they may have, with the corresponding measurements of the curves. The curves are measured by means of a plate of glass ruled with lines corresponding with the ascertained scale-value of the record, both for temperature and for time. The scale is graduated so as to read degrees vertically and hours horizontally.

Two alternative methods of reading the curves have been adopted.

- (a) At Kew the scale is set by the base-line and after hourly readings have been obtained for the whole record comparisons are made with the control readings. The residual correction so determined (normally the same for the whole record of 48 hours) is applied to the tabulations.
- (b) At Aberdeen, Eskdalemuir and Valentia, the practice is to adjust the glass scale so that the readings at the control hours on the trace are made to show general agreement with the corresponding eye-readings of the standard thermometers. The temperature equivalent of any part of the curve can then be read off. The base-line photographed on the record serves as a useful check.

^{*}At Valentia and Kew the rule is to apply the same correction for the whole chart.

[†] At Eskdalemuir the screen stands in the open.

Rainfall.—This element is recorded by a Beckley self-registering rain-gauge, in which the rain as it falls is collected in a receiver supported on a float in a vessel of mercury. As the rain passes into the receiver, the float gradually sinks, carrying with it a pen which records its position upon a chart wrapped round a clock-driven cylinder. The displacement of the mercury by the float is arranged so as to give a uniform scale throughout. When five millimetres (two-tenths of an inch) of rain have entered the receiver a siphon comes into action, and, by discharging its contents, causes the float to rise till the pen is brought back to the zero line, from which the record begins again.

The collecting funnel of the Beckley rain-gauge has an area of approximately 100 square inches. Each gauge stands on level ground and its distance from every other object is greater than twice the height of the object. The height of the rim of the Beckley rain-gauge above the surface of the surrounding ground varies from 0.4 m. to 0.6 m. at the different observatories. Details are given at the head of the tables of hourly values. A check gauge with funnel 8 inches in diameter is installed near by.

The records obtained from the Beckley self-registering rain-gauge are, if necessary, subjected to a proportional correction whereby they are brought into agreement with the amount of rainfall as recorded by the check rain-gauge which is read twice daily at, 7h. and 18h.

Rate of Rainfall.—The instantaneous rate of rainfall is registered by means of the Jardi recorder a description of which is given in *British Rainfall* 1930, Part IV, p. 284. In this instrument, rainwater collected by a funnel, I metre in diameter, enters a chamber at the bottom of which is a hole through which passes a tapering spindle attached to a float. When water enters the chamber the float rises and thereby opens the hole in the bottom of the chamber to an extent which increases as the float rises, until a position is reached when the rate of outflow is equal to the rate of inflow. The equilibrium position of the float is therefore a measure of the rate of rainfall, and the record is obtained by recording the movements of the float on a suitably graduated chart.

Sunshine.—The record of sunshine is obtained from a Campbell-Stokes recorder in which instrument the sun's rays are focussed through a 4-inch spherical lens of crown glass upon a strip of blue card, which is scorched, or burned right through, according to the intensity of the sun's rays. Three different patterns of card are used at different seasons of the year. The cards are exposed in a metal bowl, and the focussed image of the sun leaves its mark behind it as it travels along the surface of the card with the apparent motion of the sun through the heavens. The intensity of the burn is not measured, but the record is regarded as that of "bright" sunshine whenever the card has been distinctly scorched. When measuring the duration of sunshine which is represented by intermittent burns, an allowance is made for the extension of the trace by the charring of the card.

Wind - Speed and Direction.—The hourly values of wind-speed and direction which appear in this volume are derived from the records of Dines Pressure Tube Anemometers, a description of which will be found in the *Meteorological Observers' Handbook*. In the case of Aberdeen, hourly values from the Dines Pressure Tube Anemometer on the Glebe site are included for the first time. A description and illustration of the instrument will be found in the Aberdeen Sectional Introduction. At Eskdalemuir records of Dines Pressure Tube Anemometers have always been used, but at the older observatories the data printed in volumes previous to that of 1926

were obtained from Robinson cup anemographs. At Kew a new Dines Pressure Tube Anemometer, erected on the dome in the position formerly occupied by the Robinson cup anemograph, but with its vane 3 metres higher than the original height of the cups, has been brought into use from January 1st, 1931. At Valentia Observatory a new Dines Pressure Tube Anemometer, with 1-inch connecting pipes, was brought into use as from January 1st, 1932. The new instrument was erected alongside the old instrument, and a comparison extending over the period May, 1931, to January, 1932, showed that the new instrument recorded higher velocities than the old. In hourly mean values the difference was nearly uniform and equal to 4 m/s or 1 mi/hr. In gust velocities the increase was approximately 12 per cent. of the velocity recorded by the old instrument. At Eskdalemuir a new Dines Pressure Tube Anemometer with 1-inch connecting pipes was brought into use as from 11th August 1933. The diameter of the connecting pipes of the old instrument was ½ inch. Particulars of the exposure of the instruments at each Observatory will be found in the sectional introductions.

The relation between the values of wind speed recorded by the cup and pressure tube anemometers at the several observatories was briefly discussed in the General Introduction to the volume for 1926. The following table gives, for the various wind directions, the mean values of wind speed recorded by the pressure tube anemometers, expressed as percentages of the corresponding values recorded by the cup anemographs:—

Average values of the quantity $100 \times \frac{Speed\ by\ pressure\ tube\ anemometer}{Speed\ by\ cup\ anemograph}$ at the three observatories, arranged according to the direction of the wind.

Details in regard to the comparison of the new and old pressure tube anemometers at Kew will be found in the sectional introduction for the year 1931.

Minimum Night Temperature on the Grass.—This is the temperature determined by a minimum thermometer exposed freely over the surface of the grass. The stem of the thermometer is enclosed in an outer glass jacket, but the spirit bulb is freely exposed to the air. The thermometer is supported on two small Y-shaped pieces of wood so that it lies horizontally, with its bulb about one or two

inches above the ground, which is covered with short grass. When snow has fallen the thermometer is supported so as to lie just above the surface of the fallen snow, but not touching it.

The thermometer is laid out at 18h. each day, having been kept in an upright position, bulb downwards, inside the Stevenson Screen during the daytime, so that any spirit that may have condensed in the upper part of the stem may be able to run down and join the main spirit column.

Earth Temperature.—At each observatory the earth temperature is read daily at 9h at depths of 30 cm. and 122 cm. below the surface. For this purpose use is made of Symons' earth thermometers, in which the bulb is embedded in paraffin wax for the purpose of introducing sufficient "lag" to ensure that the reading will not change appreciably during the process of drawing up the thermometer in order to take the reading. The thermometers are supported at the correct depth in steel tubes sunk into the ground. At Aberdeen discontinuities have occurred on several occasions in recent years owing to changes of site. (See sectional introduction).

Notes on the Tables.

General.—Interpolated values are printed within brackets, (). Maximum and minimum values are underlined.

Standard of Time.—The observations are referred to Greenwich Mean Time except as regards sunshine, for which element local apparent time is used.

Units.—In accordance with the practice introduced in 1911, as a consequence of certain resolutions of the Gassiot Committee of the Royal Society, the values in the tables are expressed throughout in units based upon the C.G.S. System: tables for conversion to other units are given in the British Meteorological and Magnetic Year Book (Part IV) for 1913 and are also to be found in the Computer's Handbook.

Daily Mean Values.—The daily means of pressure, temperature, and relative humidity are obtained by adding half the sum of the values for the initial and final midnights to the sum of the 23 intermediate hourly values and dividing by 24.

For wind speed the tabulated hourly values are means for periods of 60 minutes between the exact hours oh and ih, ih and 2h, etc.* The daily mean is therefore obtained by dividing the sum of the 24 hourly values by 24.

In the preparation of the tables of diurnal inequalities for individual months and for the year, it is assumed that the difference of value between the means for the initial and final midnights, which may be termed, so far as the hourly variations are concerned, the non-cyclic variation, is equally distributed over the whole 24-hour period.

A note on the computation of the correction for non-cyclic change will be found at the end of this Introduction.

Annual Values.—The mean values or totals for the whole year (given either in separate tables or at the end of the corresponding monthly tables), are computed as the means or sums of 365, in leap year 366, daily values. The annual values of pressure at sea level are computed from the annual means at station level and the annual means of air temperature; the annual values of vapour pressure are derived from the annual means of air temperature and relative humidity.

Atmospheric Pressure.—All pressures recorded in this volume are expressed in *millibars*, one millibar being equal to 1000 dynes per square centimetre. The following are the values of physical constants used in evaluating the data:—

^{*} See Note, p. 19.

[†] At Eskdalemuir the annual values for the years 1922 to 1926 were computed as the means or sums of 12 monthly values.

Density of Mercury=13.5955 grams per cc. at o°C.

Intensity of Gravity at Sea Level (Lat. 45°) = 980.617 centimetres per second per second.

I inch=25.4000 millimetres.

Hence a pressure of 1000 millibars corresponds with a reading of 750.076 millimetres on a mercury barometer at temperature 0°C. in Lat. 45° and is equivalent to 29.5306 inches under standard conditions of temperature (mercury at freezing point, scale at 62° F.) in Lat. 45°.

The true pressure in millibars can only be obtained from the reading of a barometer after the latter has been suitably corrected for (a) index error, (b) temperature, and (c) gravity.

These corrections have been applied to the barometer readings in obtaining the pressure values published in this volume. The corrections for index error (including those for capillarity) are given in the certificates issued by the Kew Observatory or the National Physical Laboratory in respect of the standard barometers at each observatory. The corrections for temperature are equivalent to those published in the *International Meteorological Tables* (Gauthier-Villars, Paris, 1890). The correction for the variation of gravity from its standard value at sea level in latitude 45°, quoted above, is in accordance with the formula adopted in the *International Tables*, viz.:—

```
g_{z,\lambda}/g_{0,45^{\circ}} = (1-0.00259 \cos 2\lambda) (1-5z/4E)
where z = height of the station above M.S.L.
E = earth's radius, both expressed in the same units, and \lambda = latitude of station.
```

Except at Eskdalemuir, the correction for the variation of gravity with height, contained in the second factor of the above equation, is insignificant.

Unless otherwise stated, all pressure values refer to the level of the observatory, as given in the headings of the tables. The reduction to sea level, wherever made, is effected by tables drawn up for each observatory in accordance with the following scheme:—

If p is pressure at station level, and P is pressure at sea level, the correction required to reduce p to sea level is P-p where

 $\log_e(P/p) = gz (1-3 \overline{w}/8p)/K\overline{T}$.

z=height of station in centimetres.

e=base of Napierian logarithms.

K=gas constant for dry air=109/348.4 C.G.S. units.*

 \overline{T} =mean absolute temperature of the air column between station level and mean sea level.

w=mean value of water vapour pressure in the column.

g = mean value of the acceleration of gravity in the air column. Even at Eskdalemuir, the highest station, the effect on the correction of the variation of gravity with height is, in this case, negligible, so that

 $g = 980.617 (1 - 0.00259 \cos 2\lambda).$

The factor $(\mathbf{1}-3 \ \overline{w}/8p)$ in the above formula is practically unity except at Eskdalemuir. Its value for that observatory was discussed in the Introduction to the Eskdalemuir section for the year 1928.

In the same way, the value of \overline{T} at each observatory differs inappreciably from the value of air temperature at the observatory, except in the case of Eskdalemuir (see Introduction to Eskdalemuir section for details).

^{*} This value depends on a coefficient of expansion of dry air of 1/273 and on the density of dry air at pressure 1013.23 mb. and temperature 273°A, viz., 1293.052 g/m³.

Hence at all observatories except Eskdalemuir, no corrections are applied for the effects of water vapour, or of change of air temperature in the column of air between the station and sea level.

The scheme for correcting barometer readings outlined above was introduced for Eskdalemuir at the beginning of 1927. For the other observatories, it has come into effect as from 1st January, 1928. The effects of the introduction of the scheme on the tabulated values are briefly referred to in the several introductions to the individual sections. Only at Eskdalemuir are they at all appreciable.

The tables contain values of pressure at exact hours obtained from the photographic barograms in the manner described on p. 11; also daily, monthly and annual means of hourly values, together with the monthly and annual means of diurnal inequalities. Monthly and annual means of the hourly values after reduction to mean

sea level are also given.

There is also a table showing the daily extremes of pressure, i.e., the maximum and minimum values recorded during each day.

Temperature.—The scale on which temperatures are recorded is such that the freezing point of water under atmospheric pressure is 273°A precisely. Other temperatures differ by 273 o from readings on the Centigrade scale.

The scale approximates to the absolute scale defined by Lord Kelvin, on which the temperature of the freezing point is 273.1 to the nearest tenth of a degree.* Accordingly, to convert temperatures published in this volume to the Kelvin scale, a correction + 0.1 is to be added to each reading.

As an alternative to the application of this correction modified values may be used for the constants which enter certain formulæ. For example:—At temperature t on the scale adopted in the Year Book, the radiation according to Stefan's Lawi is

 $5.709 \times 10^{-5} (t+0.1)^4 \text{erg/(cm.}^2 \text{ sec.)}$; or $5.717 \times 10^{-5} t^4 \text{erg/(cm.}^2 \text{sec.)}$

In using the modified formulæ we are virtually adopting a scale of temperature with the degrees greater than those of the Centigrade scale, in the ratio of 273.1 to 273. This is the practice of the Computer's Handbook of the Meteorological Office.

The tables give the values of temperature at exact hours obtained from the photographic thermographs; also daily, monthly and annual means of hourly values, together with the monthly and annual means of diurnal inequalities. There is also a table showing the daily extremes of temperature.

Humidity.—When the temperature of the wet bulb is above 273°A, values of relative humidity at exact hours are deduced from the corresponding values of dry and wet bulb temperatures obtained from tabulations of the photographic thermographs, complete saturation being taken as 100. Until the end of the year 1925 the reduction was effected from tables based on Glaisher's hygrometric factors, but from 1st January, 1926, tables have been employed which proceed from Regnault's formula x = f - Ap (t - t'),

where x = vapour pressure under the conditions of observation.

f = saturation/vapour pressure at the temperature (t') of the wet bulb.

p = pressure of the air. t = temperature of the dry bulb in absolute (Centigrade) degrees.

t' = temperature of the wet bulb in the same units.

A = a constant.

The tables used in this volume for determining the hourly values of relative humidity when the wet bulb is above the freezing point are Jelineks Psychrometer-Tafeln (6th edition, Leipzig, 1911).

^{*} A. L. Day and R. B. Sosman, Dictionary of Applied Physics. Macmillan, London, 1922. Vol. I.

[†] The constant 5.709 is the value which has been adopted by the International Research Council for publication in the "International Critical Tables."

[‡] Glaisher's Hygrometical Tables, 7th edition, London, 1885. § These tables give values which are in almost exact agreement with those given by Hygrometric Tables published by the Meteorological Office in 1924 (M.O. 265) for general use at second and third order stations. The latter tables are not suited to the purposes of this Year Book, because in them temperature is expressed in Fahrenheit degrees, whereas the absolute Centigrade scale of temperature is used at the observatories.

No allowance for variation of pressure p is made and the standard value used in Jelinek's tables, *i.e.*, 755 mm. of mercury (1006.57 mb.), is adhered to. Similarly no allowance is made in the adopted value of the constant "A" for the speed of the air flowing past the wet bulb, though it is well known that "A" is not independent of the ventilation. "A" is regarded as fixed and equal to .0008. In view of the well-marked diurnal variation of wind-speed, the diurnal variation of humidity, derived in this manner, is subject to slight modification.

When the wet bulb reading does not exceed 273°A, the above method of reduction is not followed, but values of relative humidity are derived from the record of the hair hygrograph. To these values are applied appropriate corrections based on a comparison between the readings of the record of that instrument and the corresponding values of humidity computed from dry and wet bulb readings during neighbouring periods when the wet bulb readings exceeded 273°A.

The mean values of vapour pressure are computed by slide rule from a table* of saturation vapour pressure over water, and the corresponding mean values of relative humidity and air temperature.

The normal hourly values of relative humidity for the period 1886-1915, published for certain Observatories in "Hourly Values from Autographic Records, 1917," were derived from tables based on Glaisher's factors. The application of the new tables to the normal hourly values of dry and wet-bulb temperature gives results for normal relative humidity which are only slightly different from those which have been published. At Kew Observatory in winter the difference is negligible; in July it does not exceed 1 per cent. at any hour, in October it does not exceed 2 per cent. at any hour. The effect is greatest in April, when the published normal values of average relative humidity are reduced by 3 per cent. at noon and at 16h. and by smaller amounts at other hours.

Of greater importance is the effect on the values of absolute minimum humidity. Under the old system, entries of relative humidity less than 30 per cent. seldom occurred; under the new system, such entries may occur not infrequently.

Tables are printed giving the values of relative humidity at exact hours together with daily, monthly and annual means of hourly values. Monthly and annual means of vapour pressure computed from the corresponding mean values of temperature and relative humidity, together with monthly and annual means of diurnal inequalities of relative humidity, are also given.

Rainfall.—Tables are given showing for the 60-minute intervals between exact hours† the amount of precipitation, expressed in millimetres, derived from the record of the Beckley gauge (see p. 13). Totals of amount are given for each day, and for each month; the latter totals referring both to the complete days of the month, and to each of the hours of the day. When zero rainfall is assigned to a particular hour, the entry appears as "...". Corresponding totals of durations of rainfall are also given, the duration being regarded as the number of hours during which rain falls at a rate of not less than oi millimetre per hour. If slight precipitation, due to rain, snow, fog or dew, extends over some hours, and if the amounts collected in some or all of the hours are less than in mm., the fact is indicated by a succession of entries, each of which is enclosed within brackets, covering the period over which precipitation is known or believed to have occurred. In such cases entries of (i) are allocated evenly among the hours concerned in such a way that their sum is equal to the aggregate fall during the period, and the

^{*} The saturation vapour pressures used are those employed in the preparation of Hygrometric Tables. They are equivalent to those published by Scheel and Heuse in Annalen der Physik, 1910.

[†] For the years 1904 to 1920 it was the practice to tabulate rainfall for the periods of 60 minutes centred at the exact hours; the reversion to the method in use before 1904 occurred on 1st January, 1921.

remaining entries are (...), (*), (\equiv) or (\triangle) according as the precipitation took the form of rain, snow, fog or dew. Slight precipitation which takes other forms such as hail, sleet, hoar frost, glazed frost and rime is dealt with similarly. When it is impossible to determine the hourly amounts of precipitation, e.g., during snowfall or on occasions when the record has failed, the normal procedure is to consider each case on its merits, and to assign hourly values derived from estimates made by the observers as soon as possible after the event. Such values are also enclosed in brackets.

Annual totals of hourly amounts and duration and notes on special features of

the rainfall of the year are also given.

Maximum Rate of Rainfall.—The last column of the rainfall tables shows the maximum instantaneous rate of fall as registered by the Jardi recorder. When, owing to an instrumental defect, the value has been estimated from the Beckley record or otherwise, the reading is entered within brackets. When the maximum rate exceeded 5 mm./hr. the hour in which the maximum rate occurred is shown by a dagger (†) in the appropriate column of the table.

Sunshine.—Tables are given showing for each of the 60-minute intervals between exact hours* according to *local apparent time*, from sunrise to sunset, the duration of bright sunshine recorded by the Campbell-Stokes instrument. The sums and means of hourly amounts are also given. For each day is shown the total duration of bright sunshine, and also the percentage this represents of the "possible" duration for the day. The "possible" for each day is computed as the period of time beginning and ending at the instants when the centre of the sun is apparently on the horizon, due allowance being made for atmospheric refraction. Even on a clear day the sun, when at an altitude less than $2\frac{1}{2}$ ° to 3° above the horizon, fails to make a scorch on the card of the Campbell-Stokes recorder.

A distinction is made in the tables between (a) sunshine not possible, and (b) sunshine possible but none recorded. If, in any hour, sunshine is not possible, the symbol "—" is used; if more than 3 minutes of "possible" sunshine falls in the 60-minute interval between exact hours according to local apparent time, and if no sunshine was recorded, the symbol "..." is printed.

The values for the months and for the year of percentage of possible duration of sunshine are obtained by comparing the total recorded sunshine for the period with the total "possible" sunshine for the period.

Wind.—Tables are printed giving the hourly values of wind speed and direction, together with the mean speed for each day, each hour, and for the month and year. Values of speed are expressed in metres per second (1 metre per second=2.2369 miles per hour): those of direction are given in degrees from true north. The values of direction and speed are averages for periods of sixty minutes, between the exact hours of Greenwich Mean Time. They are obtained by estimation from the records with the aid of a transparent scale, with engraved graduations corresponding with the velocity, direction and time scales of the record.

When the record shows that the vane is sticking and is not responding to the variations of the wind the readings of both direction and velocity are regarded as untrustworthy and are not tabulated, the symbol "..." being entered instead. In such cases the velocity is usually less than I m/s and the symbol "..." is regarded

^{*} Before 1st January, 1921, sunshine was tabulated for the periods of 60 minutes centred at exact hours.

[†] Before 1st May, 1915, it was the practice to take the direction at the exact hour whilst wind speed referred to 60 minute intervals centred at exact hours. Thereafter until 1st January, 1932, both wind speed and direction were tabulated for periods of 60 minutes centred at the exact hours. At a meeting on 17th December, 1931, the Gassiot Committee resolved that hourly values of terrestrial magnetism, potential gradient and wind velocity and direction should be brought into accordance with the practice decided upon for Polar Year stations by the International Commission for the Polar Year 1932-1933, viz., that hourly mean values should refer to periods of 60 minutes between exact hours of standard time. (See also Introduction to Hourly Values from Autographic Records, 1913, p. xv.)

as equivalent to 0.5 m/s for the purpose of evaluating the daily mean velocity. In other cases of lost record, estimated values are entered within brackets wherever possible.

The daily values of the speed and time of occurrence of the maximum gust and the monthly distribution of wind are shown in other tables.

Minimum Night Temperature on the Grass.—Values are given for each day of the year together with monthly and annual mean values. The interval to which the reading refers is from 18h the previous day to 7h on the day to which it is entered.

Diary of Cloud, Visibility and Weather.—In these tables are given particulars of the cloud forms observed daily at 7h, 13h, and 18h, the total cloud amount observed at 7h, 9h, 13h, 15h, 18h, and 21h, the range of visibility at each of these six hours and the kind of precipitation when any was falling at those hours. There is also a column devoted to remarks on the weather of the day.

Cloud Form.—The observations of cloud form are made in accordance with the International classification, and the following abbreviations are used in the tables:—

Cirrus						Ci.			
						Cicu.			
Cirrocumulus	•••	• • •	•••	· • • •	• • •				
Cirrostratus	• • •	• • •		•••		Cist.			
Altocumulus	•••		• • •	•••	• • •	Acu.			
Altostratus	•••	• • •			•••	Ast.			
Stratocumulus	• • •				•••	Stcu.			
Stratus	•••	• • •		•••		St.			
Nimbostratus	•••					Nbst.			
Cumulus	• • •	•••				Cu.			
Cumulonimbus	•••		•••		• • •	Cunb.			
Fracto (prefix a	ıs in fr	actosti	ratus)			Fr.			
Cumuliformis (a						Cuf.			
Lenticularis (as in altocumulus lenticularis)									
Mammatus (as in cumulus mammatus)									
					•••	Mam.			
Castellatus (as	in alto	cumuli	is caste	ellatus)		Cast.			

All the cloud forms noted by the observer at the time of observation are printed where space permits. When the number of forms is too great to allow of this, the predominating forms selected at the time of observation to give the best representation of the cloud canopy are printed. If high or medium cloud can be seen, one of the selected types is normally a high or medium cloud.

Cloud Amount.—The figure given for the amount of cloud denotes the proportion of the sky covered by cloud, the numerical scale running from o, cloudless, to 10, completely overcast. The figure denotes the total cloudiness irrespective of form. In the case of fog through which it is impossible to discern the sun or stars the cloud amount is entered as 10, but if cloud can be seen through the fog, the form and amount of that cloud are entered in the usual way. If the sun or stars are visible through fog and if there is no evidence of cloud above the fog the amount is entered as 0.

Visibility.—Observations of the range of horizontal visibility made every day at 7h, 9h, 13h, 15h, 18h, and 21h, are printed in the diaries of cloud and weather.

As described in detail in the *Meteorological Observer's Handbook*, a series of selected objects, A, B, C. . . , as nearly as possible at the standard distances given in the table which follows, is used for this observation. The objects are selected so as to be readily seen and identified from specified observing points in daylight, when the air is clear. A variation up to 10 per cent. from the standard distances is considered admissible. Particulars of the objects in use at each observatory, together with a statement of their actual distances and bearings from the point of observation and notes on local peculiarities which affect the observations, will be found in the Introductions to the sections for the individual observatories.

The method of observing consists in determining which is the most distant of the selected objects that can be identified and entering the corresponding letter. In cases of uncertainty when the observer, though recognising the presence of an object, would be unable to identify its nature from the observations he is able to make at the time, the letter corresponding with the next nearer object is entered. If object A, the nearest of the selected objects cannot be identified, an entry X is made. At night the letters are used to denote as nearly as possible corresponding degrees of atmospheric obscurity.

SCHEME FOR OBSERVATIONS OF RANGE OF VISIBILITY AND OF FOG, MIST AND HAZE.

Indication Letter	Standard Distance	Verbal	BEAUFORT	LETTERS.	
of Object.	of Object.	Description.	Detailed Scale.	Contracted Scale.	
(X)	Metres.	Demon for	8 f)	
. A	25	Dense fog	7 f	F	
В	50	This to	6 f	r	
c	100	Thick fog	5 f	J	
D	200	Fog	4 f	} f	
E	500	Moderate fog	3 f	} '	
F	1,000	Mist, haze or very poor visibility	m or z	m or z.	
G	2,000	Poor visibility	1		
Н	4,000	NF- 3 4 1 11 11 4	m _o or z _o	m_o or z_o	
I	7,000	Moderate visibility]		
J	10,000	Good visibility			
K	20,000	¥7 3 - 2 - 11 - 212A			
L	30,000	Very good visibility			
M	50,000	Excellent visibility			

Note.—The grouping of the letters by the horizontal lines indicates the limits of the several figures of the International Telegraph Code for visibility, from 0 to 9, which grouping is also adopted in the tables of frequencies published in the *Monthly Weather Report*.

Small letters are used to indicate interpolations or extrapolations made in cases where it has not been possible to find suitable objects within 10 per cent. of the standard distances. In such cases the observer may use objects at other than the standard distances to guide his judgment. Particulars of such auxiliary objects will be found in the sectional introductions.

At Valentia, visibility is recorded in both landward and seaward directions. The observations of visibility landwards are printed in the main tables. Particulars of occasions when visibility seawards differed from visibility landwards are set out in the Introduction to the Valentia Section.

^{*} Not used in this Year Book.

Fog, Mist and Haze.—The table of standard distances of visibility objects also summarizes the descriptions used in connection with the phenomena of fog, mist and haze, and relates them to the scale of visibility. It also contains the Beaufort letters used for these phenomena in the Remarks column of the diary. In this Year Book as in other publications of the Meteorological Office, statistics of fog, mist and haze are based solely on visibility observations. The term fog is restricted to occasions when the visibility is less than I kilometre (i.e., object F not visible); the terms mist and haze to occasions when the visibility is greater than I kilometre, but less than 2 kilometres (i.e., object "F" visible, but "G" not visible). The distinction between mist (m) and haze (z) is determined by the depression of the wet bulb. When the visibility is between the limits specified for mist or haze, haze is recorded when the depression of the wet bulb is more than I°F; if the depression of the wet bulb does not exceed this limit, the term mist is used.

In volumes previous to 1926, occasions of haze, mist and fog were indicated by the International symbols for these phenomena, viz., ∞ , \equiv and \equiv respectively, but the relation of these terms to the visibility scale was less rigorous. In order to indicate that a change in procedure has occurred in this matter, the three International symbols for haze, mist and fog are no longer used.

Precipitation.—Whenever precipitation is falling at one of the six hours of observation there is printed in the Diary of Cloud and Weather under the heading "Precipitation" the International weather symbol which indicates the kind of precipitation, in accordance with the list below.

Remarks.—For the purposes of the column headed "Remarks on the Weather of the Day," it is usual to consider the day as divided into three portions, viz., morning, afternoon and night, denoted by a, p, n, respectively, but it should be noted that no arrangements are made for regular eye observation of weather changes in the period 21h 30m to 6h 30m.

The entries in the remarks column consist very largely of international weather symbols and the letters of the Beaufort scale. These symbols and letters are as follows:—

         passing showers.
                                                              mirage.
         drizzling rain.
```

^{*} To indicate varying intensities of haze, mist and fog the notation shown in the last two columns of the table on p. 21 is used.

The letter i preceding a letter or symbol which denotes some form of precipitation indicates that the precipitation is of an "intermittent" or "occasional" character.

The letter j preceding a letter or symbol which denotes some form of precipitation indicates that the precipitation is within sight, though not actually falling at the station.

The figure 0 written after and above a symbol indicates slight, whilst the figure 2 indicates strong or heavy; thus \bullet^0 slight rain, \bullet^2 heavy rain. The figures 0 and 2 written after and below the letters of the Beaufort notation are also used with a similar significance, thus d_0 stands for slight drizzle.

The letters b, c, o, g and u, are used to describe the general appearance of the sky. The use of the letters g and u is sufficiently clear from the definitions given above. o is used whenever the sky is completely overcast with a uniform layer of thick or heavy cloud; c is used to denote that there is some cloud present, but o is not appropriate; b denotes that there is some blue sky.*

In order to meet difficulties which occur when there are only small quantities of cloud or blue sky present, c is not used unless the sky is more than a quarter covered, and b unless there is more than a quarter of the sky free from cloud. If there is more than a quarter of the sky covered with cloud and more than a quarter of the sky free from cloud b and c are both recorded.

Up to 1931 the gale symbol was used in this publication to indicate that the wind as recorded by the anemometer averaged at least 17.2 m/s for one or more "centred" hours. At Kew Observatory the symbol has been used with the word gust in brackets to indicate the occurrence of gusts reaching 17.2 m/s.

The symbol is now used to indicate occasions when the mean velocity reached or exceeded the lower limit corresponding to Beaufort Force 8 at any time in the 24 hours of the civil day. The lower limit of velocity is dependent upon the "effective height" of the anenometer (see *Meteorological Magazine* 67, 1933, p. 278). The allotted values at the several observatories are:—

Aberdeen	Eskdalemuir	Valentia	\mathbf{Kew}
17.2	17.2	17.2	18.8 m/s.

Note on the Computation of the Correction for Non-cyclic change.

The non-cyclic change is the average increase from one midnight to the next. If, as in the case of barometric pressure, curves are read at each hour G.M.T. and tabulated under the headings oh, $1h\cdots 23h$, 24h, and the means for each of the hours in a calendar month are taken out, the mean for oh, will not in general be the same as the mean for 24h. Let x_n be the mean value corresponding to hour n; then the non-cyclic change is represented by $x_{24}-x_0$. Let \overline{x} be the mean value for the whole 24 hours. In the case under consideration the value of \overline{x} is

$$\frac{1}{24} \left[\frac{1}{2} \left(x_0 + x_{24} \right) + x_1 + x_2 + \cdots + x_{23} \right]$$

 $x_n - \overline{x}$ is the "diurnal inequality" at hour n. To apply a correction for non-cyclic change we assume that the non-cyclic change arises from a steady rise or fall, entering as a linear term. The correction applicable at hour n is therefore proportional to the time reckoned from 12h and takes the form:—

$$\frac{12-n}{24} (x_{24}-x_{0})$$

the corrected diurnal inequality having the value

$$x_n - \overline{x} + (12 - n) (x_{24} - x_0)/24.$$

^{*} The present usage with regard to b, c and o dates from 1st Jan., 1926.

In the present volume the hourly values refer either to readings at the exact hour or to means for periods of 60 minutes between exact hours, i.e., centering at the half hours. In the latter class of tabulations, the first hour of the day runs from 0h to 1h and the n^{th} hour from (n-1) h to nh. For the calculation of non-cyclic change we assume that the value of the variable at midnight is represented to a close enough approximation by the mean of the values tabulated for the hours preceding and following midnight, thus the mean value for the first midnight is $\frac{1}{2}$ $(x_0 + x_1)$ and for the second midnight $\frac{1}{2}$ $(x_{24} + x_{25})$, where x_0 represents the value for the hour preceding the first midnight and x_{25} represents the value for the hour following the second midnight. The value of the non-cyclic change is therefore $(x_{24} + x_{25} - x_0 - x_1)/2$. Remembering that the interval from noon to the middle of a tabular hour is, in this class of tabulation, an odd number of half hours, we get as the expression for the diurnal inequality at the n^{th} hour, corrected for non-cyclic change

$$d_n = x_n - \bar{x} + (25 - 2n)(x_{24} + x_{25} - x_0 - x_1)/96.$$

A correction in this form has been applied to the diurnal inequalities of terrestrial magnetism and atmospheric electricity printed in this volume.

It will be seen that the computation of the non-cyclic change (when derived from "all days"), requires a knowledge of the value for the first tabular hour in the following year. The values of wind velocity and terrestrial magnetism for the hour o-Ih on January 1st, 1936, have accordingly been appended to the appropriate tables.

Air Ministry METEOROLOGICAL OFFICE

OBSERVATORIES' YEAR BOOK 1935

Comprising the meteorological and geophysical results obtained from autographic records and eye observations at the observatories at Lerwick, Aberdeen, Eskdalemuir, Valentia, and Kew, and the results of soundings of the upper atmosphere by means of registering balloons.

LERWICK

Published by the authority of the METEOROLOGICAL COMMITTEE

LONDON
HIS MAJESTY'S STATIONERY OFFICE
1937

LERWICK OBSERVATORY

INTRODUCTION

GENERAL REMARKS.

In 1919 the establishment of an observatory in the Shetlands was included in the programme of the Meteorological Office. A wireless station, built in 1913 by the Admiralty and transferred after the war to the Post Office, but used by that Department only in case of emergency, offered suitable accommodation in the way of offices and living quarters. It proved possible to make an arrangement under which the Air Ministry has the use of the station as an observatory.

The Observatory was opened on the 7th June, 1921, when the first instalment of the instrumental equipment arrived. Later on in the same year the construction of a magnetograph house and of huts for absolute magnetic and auroral observations was commenced. The magnetograph house is a heavy concrete structure with walls 2 feet 6 inches (76 cm.) thick, of internal dimensions 16 feet by 10 feet (4.9 m. x 3 m.), and after construction several months had to elapse before the thick concrete walls and roof could be thoroughly dried and the recording instruments placed in position. instruments, which are described below, consist of magnetographs recording magnetic declination and horizontal and vertical force. More recently subsidiary magnetographs recording the same elements have been installed in one of the adjacent non-magnetic huts; the records obtained therefrom are used to cover lacunæ in the standard traces or for special investigations.

Other instruments installed at the Observatory included barometers, barograph, hygrograph, psychrometers, nephoscope, rain-gauges (ordinary and self-recording), sunshine recorder and Dines Pressure Tube Anemometer and, later, an electrograph; and in 1928 a Krogness auroral camera. But meteorological observations have been restricted, and the time of the somewhat limited staff available has been devoted chiefly to magnetic work, to some work in atmospheric electricity and latterly to auroral photography.

The site and the work in Atmospheric Electricity and Terrestrial Magnetism will now be described.

SITE

The Observatory is situated on a ridge of high ground about a mile and a half (2.4 km.) to the south-west of Lerwick and adjoins the main road between Lerwick and Scalloway. The site slopes upward from west-north-west to east-south-east, the average height above M.S.L. being about 280 feet (85 metres). The ground to the east and south-east rises slightly for about \frac{1}{4} mile (.4 km.) then slopes sharply down to the sea. In other directions there is a downward slope for about \frac{1}{4} mile extending to the Loch of Trebister on the south-west, Sandy Loch to north-west, and to the Burn of Sound to north-north-west; beyond these and distant about \frac{3}{4} mile (1.2 km.) from the Observatory are small hills - Munger Hill to the south is about 320 feet (97 metres) above M.S.L., Shurton Hill to west-north-west rises to 576 feet (176 metres), and Stony Hill to the north to about 400 feet (122 metres). In clear weather it is possible to see the Outer Skerries, 25½ miles (41 km.) north-east by north, and Sumburgh Head, 20 miles (32 km.) south by west; the horizon in other directions is limited to a few miles.

The average depth of soil in the vicinity is about a foot, and outcrops of sandstone occur in many places. The surrounding country is barren and desolate, the vegetation being chiefly coarse grass, stunted heather and moss, with occasional patches of bare black peat. The Observatory ground is of a very uneven nature and owing to lack of proper drainage is frequently waterlogged. Views of the station and a map of the surrounding country are shown in Figs. 1, 2 and 4 and the arrangement of buildings and situation of instruments are set out on a site plan in Fig. 3.

ATMOSPHERIC ELECTRICITY

Notes on the Instruments.- The records of potential gradient are obtained from a Benndorf electrograph (No. 108, by L.Castagna, Vienna) which since 1926 has been installed in the west corner of the Office Block.

Though there is distortion of the equipotential surfaces by adjacent houses etc., and though the site is a comparatively large distance (236 metres) away from the ground where absolute determinations are made, yet the values of the reduction factor suggest that these disadvantages are less serious than might be anticipated.

The collectors are of polonium deposited on a copper rod, about 4 cm. long by 0.5 cm. diameter; these are recoated periodically by arrangement with the Government Chemist, and a fresh collector is brought into use on the first day of each quarter. The collector is screwed into the end of a tube which projects about 120 cm. through a window in the north-west wall, at 190 cm. from the corner of the building and 476 cm. above ground. The inner end of the tube passes through a hole in a wooden box in which it is supported horizontally by two metal rods embedded in sulphur. A number of small 2-volt electric bulbs are kept burning inside the box in order to improve the insulation of the supports for the collector rod during wet weather, and a similar bulb is placed inside the case of the electrometer. The rod is connected to the base of the acid pot of the Benndorf electrometer by a fine wire.

detailed descrpition of this instrument is to be found in "Phys.Zeit" 7 (1906), p. 98, whilst the general principle is described in Mathias! "Traité d'Electricité Atmospherique et Tellurique," p. 54, and in Chauveau's "Electricité Atmosphérique," pp. 61-64.

The record consists of a series of dots made once a minute on a long roll of paper as it is unwound from a drum by clockwork, exact hours being indicated by dots near the edge of the sheet. Timing is taken from electric clock No. 1,031, governed by the Obsarvatory standard, Shelton No.35. The needle of the electrometer is earthed at least once daily, and a zero line is obtained by connecting up these earth marks; owing to the constancy of the perpendicular distances between the zero line and the line through the hour marks, further intermediate positions of the zero are easily obtained. The scale value has been about 24 volts per millimetre, which permits a range from + 1550 to - 1550 volts per metre in the open to be recorded.

Combined tests of the insulation of the system and scale value of the record are made daily, the procedure being to remove the collector and to charge the needle, which is connected to a Wulf electrometer. The rate of leak is obtained for a period of 4 minutes with a positive charge and for the same interval with a negative charge. Considering the climatic difficulties the behaviour of the instrument in the matter of insulation has been very satis-The rate of leak has been in general small, the average during 1935 being such that the instrument would lose half its potential in 46 minutes. It has been found that the scale value remains reasonably steady and may, for all practical purposes, be taken as constant across the full width of the sheet. The factor by which the recorded potential must be multiplied for conversion into potential gradient in the open is obtained from absolute measurements above a levelled piece of ground near the old site of the electrograph (see An insulated wire, stretched horizontally between two site plan Fig. 3). stout wooden posts about 9m. apart, carries at its centre a burning fuse exactly 1 metre above the ground. A Wulf electrometer, usually No. 5225 (Gunther & Tegetmeyer, Brunswick), is connected to one end of the wire and twenty to thirty readings are obtained from the electrometer at half-minute intervals. The reduction factor is deduced from the mean of these values and the corresponding mean potential at the collector as recorded by the Benndorf electrograph. Smoothed monthly means of the factors so obtained are employed in reduction of the records. The calibration of the Wulf Electrometers is checked periodically, using a Gambrell potentiometer and st andard cells. There was no change in any essential part of the apparatus or in the observational technique throughout the year 1935.

Tests of the rate of rise of potential of the Benndorf recorder with a polonium collector were made in September, 1930, and it was found that the potential rose from zero to half the final value in about 4 seconds. Sometimes when there is no wind the rate of rise of potential is very much slower and apparently nearly linear. If the instrument rises through a potential V and has a capacity C* a quantity of electricity CV has to be given to the air in the neighbourhood of the collector, and in the absence of wind and the presence of fog this may hang about in the form of a heavily charged cloud for a considerable time before being dispersed. Fortunately these conditions are rare at Lerwick except in early summer.

If we assume the leaking and the charging to be exponential, i.e.,

$$If \frac{dV}{dt} = - K_1 V$$
and
$$\frac{d(V_0 - V)}{dt} = K_c (V_0 - V)$$

where K_1 measures the rate of leak, K_C " " charging, and V_O is the potential of the air near the collector,

then the potential finally acquired by the instrument is $V_0 K_c/(K_1 + K_c)$.

The ratio K_1/K_C is only about 1/600 so that there is no appreciable error in the readings from this cause.

^{*} The capacity was measured in October, 1930, and found to be approximately 75 cm.

In the mean for the years 1927-33 the exposure factor shows a maximum of 1.33 in June and a minimum of 1.25 in January with secondary maximum of 1.32 in September and secondary minimum of 1.28 in August. In individual years however the variations are somewhat irregular. The vegetation in the vicinity of the site for the absolute observations changes very slightly throughout the year and the grass on the site itself is kept short. A larger contribution to the variations of the factor is probably made by a combination of effects due to pecularities of the electrograph site and wind direction. In this connection the following table shows the mean values of the exposure factor for 1927-33 summarized according to wind direction:-

	Calm	N	NE	E	SE	S	SW	W	NW	1927-33
Mean Factor	1.32	1.31	1.31	1.26	1.26	1.33	1.31	1.30	1.27	1.30

Relatively high values of the factor are on the average associated with winds from north and north-east, south and south-west and with calms. The courtyard is open at the north-east and south-west sides and the electrograph is situated near the open south-west side. The exposure in other directions is obstructed by buildings, and the depression of the factor, resulting from the higher potential of the collector when shielded from the wind, would be in agreement with R.A. Watson's conclusion that potential gradient is inversely dependent upon wind speed. (Geophysical Memoir No. 38).

On 28th June, 4th July, and 12th September, 1928, measurements were made of potential gradient above fairly smooth ground near sea level. The determinations on the two earlier dates were taken at the Point of Trebister, $2\frac{1}{4}$ km. south-south-east of the Observatory, those on the third near the Sands of Sound, 1 km. to the east. In all, ten series of observations were obtained. The mean electrograph exposure factor computed therefrom works out at 1.36, a value in close agreement with the standard determinations.

IDENTIFICATION NUMBERS OF INSTRUMENTS USED IN 1935.

Review of Results.- Days when there was a complete trace have been classified as follows by means of an electric character figure:-

- O, denotes a day during which, from midnight to midnight, no negative potential was recorded.
- 1, denotes a day with excursions to the negative not amounting in the aggregate to more than three hours.
- 2, denotes a day with negative potential amounting in the aggregate to more than three hours.
- a, denotes that the range of potential gradient in the open did not exceed 1,000 volts in any of 24 hourly periods of the day.
- b, denotes that this range was exceeded in at least one, but in fewer than six, of these periods.

c, denotes that this range was exceeded in six or more of the hourly periods.

The character figures so assigned are given in Table 4.

In the Observatories' Year Book for 1928, for the first time, this table contained also details of the duration of negative potential for each day for which an estimate could reasonably be made. If the record failed when no precipitation fell it was assumed that the potential gradient remained positive; if, however, precipitation fell when part of the record was lacking no estimate was made except when the part of missing record was small enough and the conditions of precipitation sufficiently continuous to permit the interpolation of the gradient conditions from those obtaining before and after the break.

In the year 1935 there were 46.5 hours more negative potential gradient than in 1934, and three fewer days on which negative gradients occurred. The daily mean duration of negative gradient was thus 1.80 hours, against 1.66 for 1934, 1.32 for 1933, 1.53 for 1932, 1.52 for 1931, 1.55 for 1930, 1.55 for 1929 and 1.63 for 1928. In each year the month-to-month variations of mean duration of negative gradient and of mean electric character figure show a close relationship to the variations in rainfall.

Curves are read by use of a mean value glass scale graduated in millimetres, the tabulated values being 60 minute means between exact hours G.M.T. The ordinates are converted into volts per metre in the open by multiplying by the product of the appropriate scale value and reduction factor. Values are assigned for the hours ending at 3h, 9h, 15h and 2lh, on all days, and for each hour on "a" days.

An indication of the characteristics of indeterminate potentials may be obtained from the tabulations, in which:-

- 1. Values prefixed by the symbols > , < , indicate that for one or more periods during the hour potential passed beyond the range recorded by the electrograph.
- 2. z is marked against hours when the potential passed beyond the recorded range in both directions.

The values for the hours ending at 3h, 9h, 15h, and 2lh are given in Table 1; estimated values, enclosed within brackets, are given in cases where the record was in some manner defective; a dash is entered against hours for which no value can be given with any degree of assurance. Two sets of mean values are given:— "a" The means of all positive values; hours when the trace passed off the top of the sheet are included in obtaining these means, the upper limit of registration being taken as the value for the period not recorded. "b" The means for all days on which all four hours were completely recorded or could be estimated.

In all months the general "a" mean from the four selected hours exceeds the "b" mean, the difference over the year as a whole amounting to 23 v/m. In seven months the means from the Oadays are greater than the "a" means; over the year as a whole the Oa day mean is 6 v/m greater than the "a" mean. The

annual mean daily values derived in these three ways for the nine years 1927-1935 during which the electrograph has been in the same position are:-

			0a	"a"	uPu
1927	• • .	••	213 v/m	179 v/m	160 v/m
1928	• •	• •	166 v/m	156 v/m	134 v/m
1929	••	• •	162 v/m	161 v/m	133 v/m
1930	• •	• •	181 v/m	175 v/m	158 v/m
1931		• •	161 v/m	163 v/m	147 v/m
1932	• •	• •	159 v/m	159 v/m	141 v/m
1933	• •	• •	168 v/m	170 v/m	152 v/m
1934	• •		188 v/m	182 v/m	159 v/m
1935	•. •	• •	165 v/m	165 v/m	142 v/m

It is a defect of the Benndorf recorder that even with such a high scale value as 24 v/mm the width of the sheet is frequently exceeded during oscillatory movements. In 1935 there were 99 days on which the electrometer needle went beyond the limits of registration on the positive side and 151 on the negative side; these occasions were mainly when precipitation was falling on the collector. The greatest number of extreme positive excursions were associated with snow or sleet showers and were almost invariably only momentary.

The following are the occasions of potential gradients (positive and negative) exceeding 1000 v/m persistent over periods of at least one hour, a specified hour defining the 60 minute interval ended at the exact hour G.M. Ta-

Positive. August 19d 23h.

C

Negative. March 3ld lh; April 22d 3h and 23d 7h; May 5d 18h; Nov. 15d 13h and 24d 3h.

Occasions when the potential gradient was negative for prolonged periods with perhaps only a few temporary changes to positive were noted as follows:-

- (1) March 30d 22h 45m to 3ld 8h 35m. Negative for all but 3 mins. Mean gradient < -685 v/m. Continuous moderate rain.
- (2) Apr. 23d 2h 25m to 13h 40m. Negative for all but 20 mins. Mean gradient < -668 v/m. Continuous slight rain.
- (3) May 15d 4h 15m to 9h 57m. Negative throughout. Mean gradient < -658 v/m. Continuous slight rain.
- (4) August 25d 23h 45m to 26d 7h 45m. Negative for all but 6 mins. Mean gradient < -783 v/m. Continuous moderate rain.
- (5) Oct. ld 6h 45m to 14h 15m. Negative for all but 7 mins. Mean gradient < -637 v/m. Continuous slight rain.
- (6) Oct. 5d 6h 0m to 15h 5m. Negative throughout. Mean gradient < -510 v/m. Continuous moderate rain.
- (7) Nov. 23d 22h Om to 24d 5h 30m. Negative for all but 4 mins. Mean gradient < -719 v/m. Continuous slight rain.

Notable spells of high potential were:-

```
June 22d 14h to 21h.

```

There were 75 days on which there occurred apparent changes of potential gradient from the limit of the sheet on the positive side to the limit on the negative side, at least once within an interval of 60 minutes. If these changes were real and not due to charges given to the collector rod by precipitation, they connote a range exceeding 3100 v/m within anhour. Assuming that in Shetland the charge associated with rain may occasionally attain 10 E.S.U. per cc., it has been found that the gradient recorded may contain a contribution of not less than 50 volts arising from the charge given by the rain. In some of the hours the extreme reversal occurred at least twice within the period.

The diurnal inequalities for Oa days for the months, seasons, and year, are given in Table 2, together with mean values of the potential gradient and particulars of the non-cyclic change and the number of days used; the inequalities and other entries for the seasons and year are the means of the corresponding entries for the appropriate months. Similar data for the la and 2a days together are given in Table 3.

The annual mean diurnal variation for Oa days during 1935 has a minimum at 3-4h and a maximum at 16h. The 12-hour component is not well marked, though it is clearly seen in the inequalities for equinoxial and summer months. The range is largest and the maximum occurs earliest in winter, the smallest range being in summer.

The inequalities for la and 2a days are similar in shape to those for Oa days, and of about the same range, but in the mean for the year the 12-hour variation is more clearly developed, owing to the augmentation of the morning maximum in summer.

TERRESTRIAL MAGNETISM.

Notes on the Instruments.

Up to April 20th, 1934, the standard records of declination (D) and horizontal force (H) were obtained from the Munro magnetographs, which were in use at Falmouth until 1912, and those of vertical force (V) from the Watson quartz fibre instrument, which at the end of 1929 had replaced a Munro variometer.

Early in 1934 a complete magnetograph set of the la Cour type was received. This set had been used by the British Polar Year Expedition at Fort Rae, Canada during 1932-33. It was installed in the magnetograph house and was adopted as the standard on April 20th, 1934, the former standard set becoming the auxiliary.

The la Cour set consists of H, D and V variometers. The H and D magnets are about 1 cm. in length, and each is supported by a single quartz fibre. A description of the H variometer is given in Publikationer fra det Danske Meteorologiske Institut, Communications Magnétiques, No. 11 (le Variomètre de Copenhague). The V magnet is larger; it is supported by knife edges resting on agates, and is enclosed in a sealed vessel under reduced pressure. A description of this instrument is given in Pub. fra det Danske Met. Inst., Communications Magnétiques, No. 8 (la Balance de Godhavn).

The recording apparatus is so designed that the three elements are recorded on one sheet of photographic paper, with a single electric lampas source of light. Time marks are made by a second lamp, the circuit of which is closed by a clock for about 10 seconds every five minutes. The width of paper is 10 cm. for each element, but the effective width is increased by a number of small prisms which reflect light from the lamp into the variometers, producing a series of light-spots at intervals of slightly less than 10 cm.

Scale values of H and V are measured by passing a current through Helmholtz-Gaugain coils placed over the variometers, the resulting deflexions being recorded on the photographic paper. The current is measured by a small milli-ammeter (Weston, No. 55896), which is periodically calibrated It is thought that the scale values adopted are accurate within 1%; these were about 4.2 γ /mm for H and 5.8 γ /mm for V. The scale value of D depends only on the geometry of the system, with a small correction for torsion, and is 0.95/mm.

The H and V variometers are capable of accurate compensation for temperature, but neither was completely compensated during 1935, the adjustment of the V instrument, which was correct in 1934, having been upset during other alterations at the end of that year. Allowance is made in the base values for the small residual temperature coefficients. Apart from this, base values of all three records have been very steady.

In July 1935 a la Cour quick-run magnetograph set was installed; this also had been used by the British Polar Year Expedition. The variometers are similar to those of the standard set, but the time-scale is twelve times as great.

The standard records of declination, horizontal force and vertical force have been tabulated hour by hour. The values are read off by means of graduated glass scales, a value being the mean for 60 minutes between exact hours G.M.T.

Base values for the records are obtained from the results of absolute observations, the determinations of horizontal force being made twice, those of declination and dip six times in each week. Horizontal force and declination are determined with the unifilar magnetometer on the centre pillar (No. 2) of the absolute hut, the azimuth of the fixed mark being taken as 8° 43′ 2° east of south. In the deflection experiment three distances, 25, 30 and 35 cm., are used for obtaining the distribution coefficients, the horizontal force being computed from the deflection at 25 cm. only.

Mean annual values of the P and Q correction have been derived from observations during the period March 1923 to the end of 1935. An accident caused some change to the magnet in March 1923, and values for earlier months have been discarded.

The values during these years are as follows:-

1923 (March-December) -2.40 -30 1.99830 1924 -1.24 -481 99860 1925 -1.17 -892 99820 1926 +1.23 -1727 99893).
1925 -1·17 -892 99820 1926 +1·23 -1727 99893	
1926 +1.23 -1727 99893	
1927 +2.23 -2200 99910	
1928 +0.22 -1412 99858	
19290.54 -969 99855	
19301-21 -853 99821	
19311.04 -911 99826	
1932 +1.37 -1866 99887	
19330.12 -1098 99869	
1934 +2.98 -2397 99940	
1935 +0.67 -1490 99881	

The values of P and Q and of $\log_{10}(1 + P/25^2 + Q/25^4)$ for 1934 were the largest of the thirteen year series. The collimator magnet was dropped on June 11th of that year, and the lens was cracked, but this was not the cause of the abnormal values of P and Q, since it has been found that the abnormality lies in the observations made earlier, those made after the accident giving values much closer to the means of the preceding years.

During 1935 a small error was found in one of the constants used in computing Q for every year except 1929. The correction of this error increases the numerical value of Q by $16\cdot0$ and reduces $\log_{10}(1 + P/25^2 + Q/25^4)$ by $\cdot000018$; the effect on H and V would be a reduction of $0\cdot3\gamma$ and $0\cdot9\gamma$ respectively for all years up to the end of 1934. The figures in the table above have been corrected.

The mean value of $\log_{10}(1 + P/25^2 + Q/25^4)$ employed in the reduction of

all observations for 1935 was the mean of the values derived up to the end of 1934, namely, $\overline{1} \cdot 99866$. If the 1935 value is added and the correction referred to in the last paragraph applied to all, the mean for the total available period becomes $\overline{1} \cdot 99865$. The adoption of this latter value would reduce all the hourly values, monthly means, etc., as given in the tables by 0.2γ in the case of H and 0.5γ in the case of V.

In the latter part of December 1934 and during part of the year 1935 observations were made with Circle No. 120, and needles Nos. 239/1, 2, 3 and 4.

In April 1935, with the kind permission of the Astronomer Royal, the earth inductor which had been in use at Fort Rae during the Polar Year was borrowed again from the Royal Observatory, Greenwich and sent to Lerwick. Comparative series of observations showed that the Greenwich inductor (with the recommended correction of +10.7" added) led to values of V slightly different from those given by the mean of the dip needles, and in July 1935 it was decided to adopt the standard given by the inductor and to determine base line values of V for the earlier part of 1935 by applying a constant correction to the values derived from the dip circle.

As stated in the general remarks, the walls of the magnetograph chamber are of concrete, 76 cm. in thickness. The diurnal variation of temperature within the chamber is, for most days of the year, negligibly small and no corrections for this diurnal variation have been applied to the diurnal inequalities or other data published in this volume. From the magnetograph house temperatures for each day given in the Table's, however, it will be noted that the day-to-day change of temperature is sometimes considerable. The average day-to-day change in degrees absolute over each of the twelve months of 1935 and for the year as a whole was as follows:-

Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec. Year 0.42 0.49 0.30 0.27 0.45 0.35 0.34 0.28 0.29 0.42 0.27 0.33 0.35

There were 19 occasions on which the change reached or exceeded 1°A.

The results of the absolute determinations of D, I and H are summarized in the subjoined table, and the values of m, the moment of collimator magnet 395LA are also given. It should be noted that the values obtained are affected to an appreciable extent by changes of H between the vibration and deflection experiments. Considerations of space make it necessary to limit observations printed to about two per week, but, as indicated above, absolute observations of D and I are made more frequently. For each set of absolute observations are shown the deduced base line values of H, D and V, and, in brackets, the adopted base line values. Thus, the entry 428 (427) under H signifies: deduced base line value 14,428, adopted base line value 14,427. The adopted values were obtained as described in the foregoing, and therefore the base line values corresponding to dates between those given in the table may be obtained by interpolation.

table on p 21 of the Observatories' Year Book 1938 are 5 y too low. This means that the values originally published are only 1 y too high.

ABSOLUTE DETERMINATIONS OF D, I AND H, AND BASE LINE VALUES OF H, D AND V.

AURORA

From about September to April a watch for aurora is maintained, normally until about 23h G.M.T. each evening, and observations - as a rule at intervals of 15 to 20 minutes - are made of the northern horizon and of general meteorological conditions. The records form what is called the auroral log, a brief summary of which is given in Table 67. When any auroral display is observed, a second observer is called and detailed observations are maintained until the display subsides. These detailed observations have consisted in noting and making descriptions of the phenomena seen during the display, and have been supplemented whenever possible by photographs taken with the Krogness camera. The descriptive notes are entered in a second log reserved for records of actual auroral displays. Extracts from this latter log may be obtained by anyone requiring the detailed information.

A general auroral table for Scotland (Table 68) is also included This table has been compiled from the records of all stations at which climatological observations or weather logs are maintained. The observers at these stations, whilst noting occasions of aurora which they may happen to observe, do not in general maintain a special watch.

Notes on the Tables.

The hourly values of H, D and V, obtained as described above, appear in three of the four monthly tables. The variations in D, being expressed in minutes, may be readily converted to units of force (γ) of the component perpendicular to the magnetic meridian by multiplying by a factor which for 1935 is approximately 4.20. The mean value for the day is computed as the mean of the twenty-four hourly values.

The letters "Q" and "D", prefixed to dates, denote the five quiet and the five disturbed days as selected at De Bilt.

In the fourth table for each month are given: -

- (a) The values and times of the daily maximum and minimum and the values of the absolute daily range for each of the elements H, D and V.
- (b) The value of $HR_H + VR_V$ for each day, where R_H and R_V denote the absolute ranges in force for a calendar day of the horizontal and vertical components.
- (c) The daily magnetic character figures, assigned according to the international scheme wherein "0", "1", "2", respectively, denote quiet, moderately disturbed, and highly disturbed conditions.
- (d) The daily values of temperature in the magnetic chamber.

Mean diurnal inequalities of H, D and V on all days and on international quiet and disturbed days are given, for the months, seasons and year, in Tables 53 to 61.

In calculating diurnal inequalities the non-cyclic change has been eliminated on the assumption that its time rate is linear. The values of the range of the mean diurnal inequalities of the several elements in the three categories of days are brought together in Table 62, and the values of the

non-cyclic change are given in Table 64. The "Average Departures", or mean values of the 24 hourly constituents of the inequalities irrespective of sign, are given in Table 63.

The mean values of HRH + VRV are summarized in Table 65.

In earlier years Table 66 gave, for the months and year, the mean values of N, W, V, D, I, H and Total Force T on all days. Since 1934 the Table has been extended to give in addition the mean values of the primary elements H, D and V on the internationally selected groups of quiet and disturbed days. For all days the means of N, W, I and T are derived from the corresponding values of H, D and V.

Finally, in Tables 67 and 68 are given summaries of auroral observations obtained as already described.

Review of Results.

Mean and Extreme Values of the Magnetic Elements, 1935.—The mean values of the magnetic elements for the years 1934 and 1935 are given in Table 1. The values of H, D and V have been computed from the hourly values derived from the autographic records of all days, standardized by means of the absolute observations; those of N, W, I and T have been deduced from the values of H, D and V.

 Year	Н	- (1	D West)		I	N.	W	٧	T
	Y	0	,	0	,	Ψ.	Y	Y	Y
1934 1935	14463 14446	13 13	21. 9 9.5		48•4 49•9	14071 14067	3343 3289	46744 46758	48930 48939

TABLE 1.

The annual rates of decrease of westerly declination for the epoch January 1st of each year during the last ten years are summarized as follows:-

	1924	1925	1926	1927	1928	1929	1930	1931	1932	1933	1934	1935
Annual rate of		1	-	7	1	1	1	1	1	1	1	1
decrease of W	13.8	13.0	14.9	12.9	12.8	13.7	12.4	11.6	13•6	12-1	12.1	12-4
declination on							·					
Jan. 1st.												

In comparing the values of I, V and T for the two years in Table I with those given in the corresponding table for earlier years the discontinuity of +3' in I or $+144\gamma$ in V on Jan. 1st 1934 is to be borne in mind. (See O.Y.B. 1934, p.35).

Mean values derived from (a) international quiet days and (b) international disturbed days are as follows:- (a) H, 14449γ; D, 13° 9'.6; V, 46759 (b) H, 14441; D, 13° 9'.3; V, 46756.

The extreme values of H, D and V recorded during 1935 are given in Table II.

		TA	BLE	II,		,	·.	
	Ma.	ximum		N	linimum			Absolute
Element	Value	Date 1	935	Value	Date	19	935	Annual Range
Horizontal Force	14784 γ	d h Oct.24 14		13709 γ	d Jun. 7	h 22	m 10	1075γ
Declination	140 5.5	Jun.18 19	38	120 13:3	Jun. 8	2	30	10 52-2
Vertical Force	47032 y	Oct.27 19	35	46353	Jun. 7	22	31	679 Y

The range of 1° 52.2 in declination is equivalent to a range of 47l γ in the component of force perpendicular to the magnetic meridian. In the year 1934 larger ranges were recorded in H, and V.

Magnetic character of the year. The following table shows the mean sunspot numbers for recent years, together with the mean absolute daily range of declination, as a rough measure of magnetic activity:-

Year	1923	1924	1925	1926	1927	1928	1929	1930	1931	1932	1933	1934	1935
Sunspot No.	5•8	16•7	44•3	63•9	69•0	77-8	65•0	35•7	21.2	11•1	5•7	8•7	36 • 1
Absolute daily range of D.	1460	15 : 4	1061	2560	2060	91 64	94 63	2845	1062	91 (2	1966	1860	204

In these thirteen years the sunspot numbers show a fairly regular rise from the minimum year 1923 to a maximum in 1928 and a fall to the second minimum in 1933 after which the rise in the new cycle is small in the first year and then more rapid in 1935. The second minimum in the D ranges occurs one year after the sunspot minimum and the maxima occur in 1926 and 1930, the latter the larger, although its sunspot number was less than in 1935.

In the next table the magnetic conditions for individual months of the year 1935 are set out, together with their sunspot numbers.

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.

In addition to summarising the local and international character figures for each month, Table III gives the annual totals of the separate characters and the annual means from 1924. Comparative data for all, q and d days derived from the numerical index of disturbance ($HR_H + VR_{V}$.) 10^{-4} are given for each month of 1935 and annual means from 1930. September and October were the most disturbed and November and August the quietest months of 1935. As a whole 1935 was more disturbed than either of the two preceding years but this was due to a decrease in the number of really quiet days, not to an increased frequency of days of large disturbance.

The values of mean absolute daily range for the months and seasons of the year are given in Table IV, where for convenience of comparison, the ranges of declination in angle have been converted to units of force of the component perpendicular to the magnetic meridian. If comparison be made with the corresponding table in the Eskdalemuir Section it will be seen that in 1935 the ratios of the annual mean ranges of H, D and V at Lerwick to those at Eskdalemuir are 1.5, 1.1 and 2.3. The ratios of the mean daily ranges for the six years 1926-31 of Lerwick H to Eskdalemuir N, Lerwick D to Eskdalemuir W, and Lerwick V to Eskdalemuir V, are 1.4, 1.1 and 1.9; the greatest variation from year to year appears in the case of the vertical component; scarcely any variation appears in the ratio of the W or D component and a slight variation in the case of the H or N component.

The frequency distribution of absolute daily ranges recorded in 1935 is shown in Table V. A comparison with the corresponding figures for Eskdalsmuir (Table V. on page 187) indicates that ranges in excess of 200y are again much more frequent at Lerwick than at Eskdalemuir, even in the case of Dranges, of which the frequency distributions at the two places usually show less divergence. Apart from this it is notable that the ranges of maximum frequency at Lerwick fall in the intervals 60-69y for H and D, and 20-29y for V, that is, at much the same points as at Eskdalemuir, though V has many more ranges in excess of 200y than have H and D.

TABLE VI .- PRINCIPAL MAGNETIC DISTURBANCES RECORDED AT LERWICK, 1935.

Where the beginning of a disturbance has been marked by a "sudden commencement", the serial number is followed by an asterick (*), and the time entered in the second column is that of the sudden commencement, estimated to the nearest minute. In other cases, the exact hour nearest the time at which disturbance may be regarded as having begun is entered in the second column. To the tabulated values of maximum and minimum, the following have to be added:- H, 14,000y; D, 13°; V, 46,000y.

"Diurnal Inequalities".- The mean diurnal inequalities for all days, international quiet and disturbed days, for the months, seasons and the year, are given in Tables 53-61, and the corresponding inequality ranges in Table 62. The inequalities of H, D and V for international quiet and disturbed days are shown graphically in Plate I, whilst in Plate II are given vector diagrams illustrating the diurnal variation of magnetic force in the horizontal, the prime vertical and the meridian planes respectively.

All days.- The ranges of the annual mean inequalities of H, D and V are all higher in 1935 than in 1934; except for the range of the summer mean inequality of H the separate seasonal inequality ranges for 1935 are also all greater than in 1934.

Quiet days.- The H and D annual mean inequality ranges are greater than for any of the preceding four years but the corresponding range for V is slightly smaller in 1935 than in 1934.

In V, 1927, 1928 and 1929 had the smallest Q-day ranges, in the seasons as well as the years, 1930 considerably the largest; but in H and D the relation between the years is not so clear, 1927, 1928, and 1929 tending to have the largest ranges, 1931-33 the smallest, with the disturbed years 1926 and 1930 intermediate.

Disturbed days.— The range of the 1935 annual inequality of all three elements is greater than in 1933 or 1934. In the latter year the range in H was less than in any year since 1924 and in D and V the ranges were the smallest of all years for which comparable ranges are available at Lerwick, viz. 1923 in D and 1926 in V. In all three elements the range of the 1935 equinoctial mean inequality is greater than that for summer or winter though in H June is the individual month of greatest range.

A comparison of the records of Eskdalemuir and Lerwick shows that in general the declination inequalities at the two places for all, quiet and disturbed days are very similar in general appearance, although minor irregularities on the one set of values are not always reproduced on the other, or, if so, only with diminished amplitude. Differences are more obvious on the horizontal force curves even on quiet days; and become conspicuous in the disturbed day inequalities in H in some months. In the case of vertical force these differences are even more marked. The table below shows the ratios of the ranges of the inequalities in the various months.

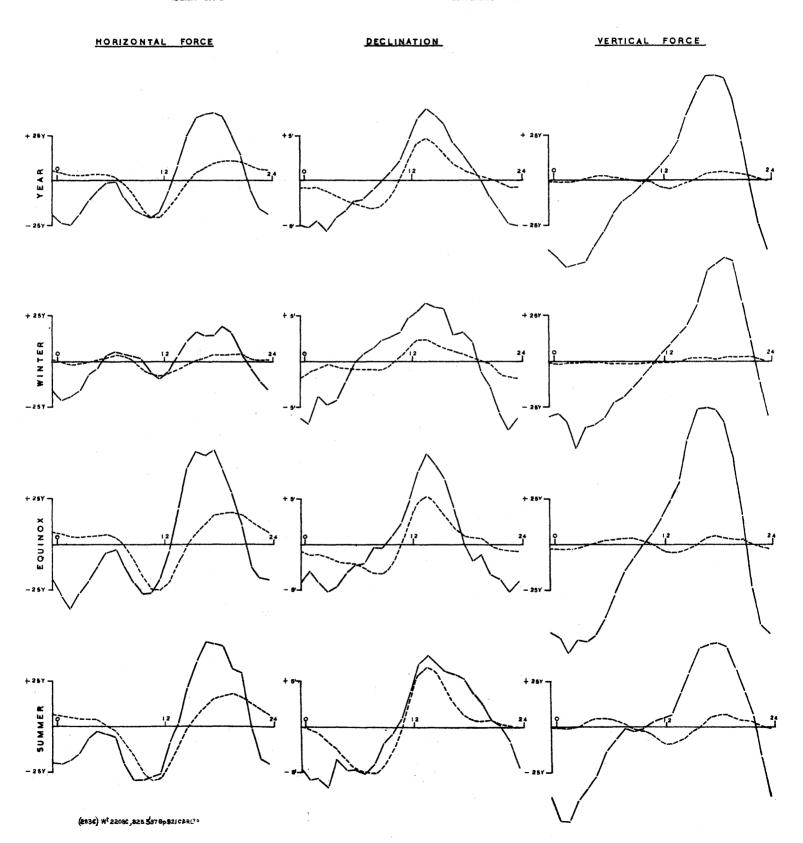

Ratio of the Range of the Inequality at Lerwick to that at Eskdalemuir (1935)

DIURNAL VARIATION OF THE MAGNETIC ELEMENTS LERWICK 1935

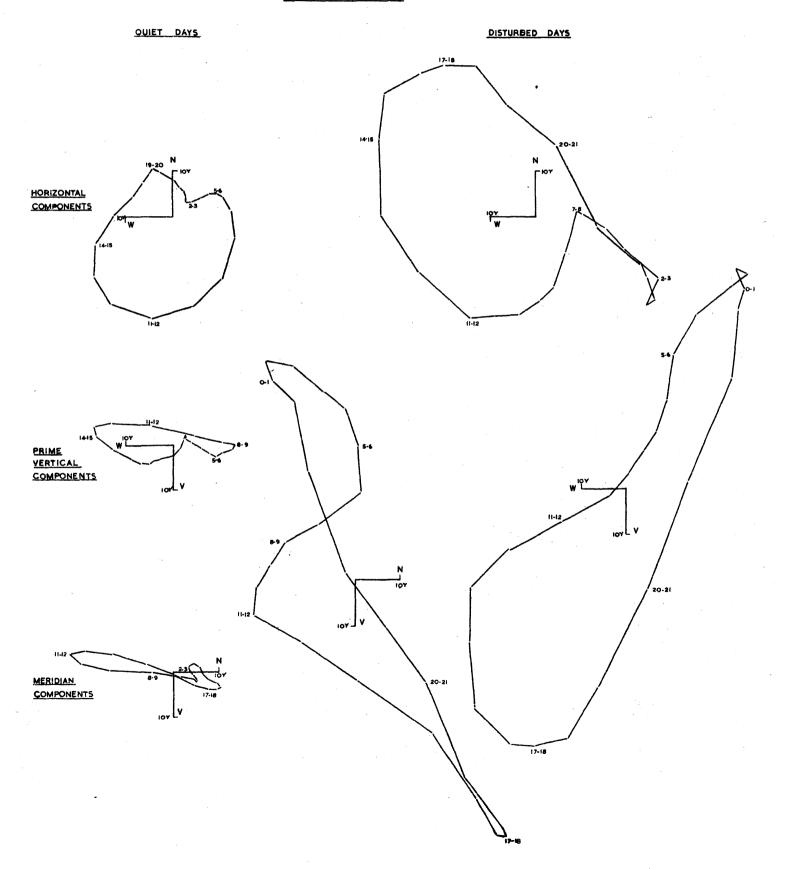

QUIET DAYS----

DISTURBED DAYS ---

VECTOR DIAGRAMS ILLUSTRATING DIURNAL VARIATION OF MAGNETIC FORCE

LERWICK 1935

Magnetic Disturbances. - Particulars of the principal magnetic disturbances recorded at Lerwick during the year are given in Table VI. In the Eskdalemuir Section will be found a similar list which deals with the same disturbances as recorded at that Observatory. Within the limits of accuracy of measurement and registration, "sudden commencements" appear to occur simultaneously at the two Observatories.

Remarks on the Autographic Records, 1935.

JANUARY .- (Average Character Figure 0.71)

Conditions were quiet throughout most of the month; the quietest periods were 10th to 14th inclusive and 29d 3h till 30d 7h. A small disturbance occurred on 17th, when between 1h and 3h there were dips of 260 γ and 200 γ in the H and V records, and irregular fluctuations in D through a range of 33'. Slight disturbance continued throughout the 17th and 18th, and again from the end of 21st till the early hours of 26th.

After a short quiet interval, there was a "sudden commencement" (-13 γ , +33 γ in H) at 27d 14h 50m. This was followed soon after 19h by a moderate disturbance, which lasted until the early hours of 28th, all three elements being somewhat below their undisturbed values. The only notable movement was a sharp dip of 300 γ in H, with minimum at 0h 55m.

Aurora was seen from one or more places in Scotland on the evenings of January 1, 4, 21, 23, 25, 27 and 28.

FEBRUARY. - (Average Character Figure 0.86)

Except during the 4th-7th, llth and 27th-28th, there was continuous minor activity throughout the month. Moderate disturbance occurred on the 1st and 2nd and the night of 13th-14th. During the night of 1st-2nd there was a marked increase in the normal diurnal variation of all three elements, as is usual during disturbance, but without the large fluctuations usually superposed; the ranges of the smoothed curves were 160 γ in H, 40' in D and 380 γ in W Disturbance was absent during the daylight hours of 2nd, but was renewed for a short time after 17h, when H and V rose rapidly but irregularly to maxima at about 19h; disturbance was then practically at an end, and H had returned to near its normal value by 21h and V by midnight.

On 13th, after some activity during the afternoon, there were rapid fluctuations in all three elements, beginning at 20h. Soon after 21h H began to fall rapidly; the fall became very rapid at 22h 50m, and a sharpminimum, 450y below the normal value for this time, was reached at 22h 55m; this was followed by a rise of 380y in the next 15 minutes. Between 22h 50m and 23h 30m there were rapid oscillations in D and V. During the first six hours of 14th there were irregular fluctuations of decreasing range, all three elements being somewhat below their normal values, and the disturbance died out gradually during the day.

Aurora was seen from one or more places in Scotland on the evenings of February 1, 2, 3, 5 and 23-26.

MARCH .- (Average Character Figure 0.84)

After slight activity during the first three days, conditions were calm from the early hours of 4th till the end of 12th. There was some disturb - ance on 13th, especially between 16h and 19h. This was renewed on 14th, the most disturbed period being from 14h to 22h.

The maxima of H and V occurred at about 16h; soon after 17h both components began to fall irregularly, reaching their minima for this disturbance shortly before 15d 2h. The ranges during 14th-15th were: H 377y, D 59'6, V 413y. Disturbance continued with diminishing intensity throughout 15th.

During the rest of the month there was some slight activity almost continuously, but the periods 22d 10h to 23d 22h and 27d 10h to 30d 12h were the most quiet. At 30d 12h 13m there was a "sudden commencement" (-18 γ , + 40 γ in H). This was followed by small and rapid oscillations until 14h 30m; the maxima of H, D and V occurred shortly after, and no further disturbance developed.

Aurora was seen from one or more places in Scotland on the evenings of March 3, 5, 7, 12, 14 and 24.

APRIL. - (Average Character Figure 0.80)

From the beginning of the month till the early hours of 8th conditions were quiet. On 10th a disturbance developed, H and V rose to irregular maxima soon after 18h; there were sharp dips in H to minima at 10d 22h 14m and 11d 1h 53m, the minimum of V occurring in a series of small oscillations between 1h and 2h. Disturbance continued throughout 11th, but movements were not very large. There was a small dip in H between 10h and 11h, followed by an irregular rise to the afternoon maximum. After 15h H and V fell slowly to minima about 22h. Between 15h and 23h there were several rather sharp dips in D, of 15' to 25'. The ranges for the period 10th-11th were: H 491y, D 49'4, V 331y. Conditions remained somewhat disturbed during 12th and 13th.

During the rest of the month there was no more than slight disturbance; the periods 20d 4h to 23d 6h and 25d 8h to 30d 6h were very quiet.

Aurora was seen from one or more places in Scotland on the evenings of April 2, 5, 8, 9, 10, 12 and 23.

MAY. - (Average Character Figure 0.77)

There were only three short periods of disturbance during the month; apart from these there was nothing more than minor activity.

Disturbance began rather abruptly shortly before 13h on 1st. Movements were at first small, though rapid, and after 16h there was a decrease of activity. After 22h, however, H and V began to fall; the fall became very rapid at 22h 52m, and sharp minima were reached almost simultaneously about 7 minutes later, the fall in this interval being 330y in H and 195y in V. There was a rapid recovery in both components, and then a further fall to minima at 24h, followed by an irregular rise until about 6h. D also fell rapidly

after 1d 22h 30m; there was a double dip with minima at 23h 24m and 23h 54m, each 45' below the undisturbed value for this hour. After 2h D rose rapidly, reaching a normal value shortly before 4h, when the disturbance was practically at an end.

There was slight disturbance from the afternoon of 10th till shortly after midnight. Agitation continued during the next three days, dying out by the end of 13th.

On 20th between 3h and 5h there was a dip of 130y in H, a dip of 170y in V and a peak of 25' in D. After returning to approximately its former value, H began to fall again at 5h 30m, reaching a second minimum at 7h 27m. There was only minor activity during the rest of the day.

Very quiet periods were: 3d 22h to 10d 3h, 14d 18h to 15d 8h, 17d 4h to 18d 8h and 24d 2h to 25d 10h.

Aurora was seen from Eskdalemuir on the evening of May 31.

JUNE. - (Average Character Figure 0.83)

Conditions were very quiet for the first three days, rather less so from 4d lh till noon on 7th. A disturbance then began to develop, which became large and lasted till the end of 11th. Between 12h and 16h there were small and rapid oscillations in all elements. From 16h till 20h movements less rapid, but H and V were above their normal values - H by roughly 50v. At 20h H and V were falling. H continued to fall at an increasing rate, but with a few pauses, to a very sharp minimum, some 770y below the normal value for the time, at 22h 10m. V oscillated rapidly within a range of 500y between 21h and its minimum at 22h 31m. The movements of D were neither large nor rapid up to 21h 50m, but it began then to oscillate rapidly; it reached its maximum for the storm at 22h 6m and minimum for the day at 22h 24m after a fall of 63' in 8 minutes, and immediately began to rise, increasing by 68' Two more dips, 1' and 7' deeper but less rapid, had in the next 10 minutes. their minima at 8d Oh 37m and 2h 30m; the latter was the absolute minimum for the storm. H and V made rapid but partial recovery from the minima, continued to fluctuate about low values until, after less deep minima, H at 8d 2h 35m and V at 2h 27m, both began an almost continuous rise to normal values, which were reached at about 5h.

Activity continued during 8th, and on the afternoon of 9th disturbance was renewed. The absolute maximum of H for the storm was reached at 15h 55m, and was followed by an irregular fall to the minimum, which occurred in a trough, some 130 pdeep, between 22h and lh. V fluctuated in a similar way. Disturbance continued during 10th, the maximum of V, at 15h 35m, being the absolute maximum for the storm, though only 4p higher than that of 7th. The disturbance subsided markedly after 20h 30m, and there were no deep minimaduring the night. Slight disturbance occurred again on the afternoon of 11th.

The ranges for this storm (7th-11th) were H 908, D 81!7, V 539y.

Conditions were very quiet from 14d 8h till 16d 8h. On 17th activity increased, and on the afternoon of 18th took place a large but brief disturb-

ance. There were large humps in H and V, with maxima in small peaks at 15h 40m and 15h 36m respectively; these were followed in each case by several slightly smaller peaks, and a gradual descent. At 19h 24m H and V began to fall very rapidly. H fell by 330 to a sharp minimum at 19h 39m, and V by 200 to its minimum at 19h 35m, the ranges between these minima and the afternoon maxima being 50ly and 375 v. Both minima were followed by a rapid recovery. Up till 19h 26m the movements in D were not large, but D then began a rapid rise, increasing by 44' to its maximum at 19h 38m, and falling by 66' in the next 24 minutes. After this time movements were not large, but there was continuous agitation of the traces until 19d 4h. There was slight disturbance on the afternoon of 19th, 20th and 21st, and small troughs in H and V, accompanied by oscillations in D, around midnight of 20th-21st.

No further noteworthy disturbance occurred and the period 21d 22h to 26d 24h was very quiet.

JULY. - (Average Character Figure 0.65)

The first seven days were quiet, especially the period 5d 20h to 7d 8h. At 7d 2lh 9m there was a small movement similar to a "sudden commencement" but less rapid (-4γ , $+37\gamma$ in H; -0.8, +5.0 in D and very small in V). An increase of activity followed, D being slightly below its normal value until about 8d 7h. Between 6h and 1lh there was a dip of 120 γ in H. Slight disturbance continued during the afternoon.

There was minor activity on the succeeding days until the end of 11th, when conditions became moderately quiet. At 14d 15h 31m there was a "sudden commencement" (-19\gamma, +68\gamma in H; -2\gamma, +5\gamma 0 in D; +20\gamma, -31\gamma in V); this was not followed by any disturbance. Conditions were quiet from the evening of 16th, and only slightly less so after the end of 18th, until the early hours of 22nd. The next 24 hours were slightly disturbed.

At 24d 20h 35m a "sudden commencement" (-2\gamma +52\gamma in H; -0'5, +1'8 in D; +5\gamma, -22\gamma in V) marked the beginning of a moderate disturbance. Between 22h and 24h there was a dip of 250\gamma in V, a small dip in H and two small dips in D. Another dip in V, of 310\gamma, between 25d 0h 30m and 3h was accompanied by a sharp dip of 300\gamma in H and oscillations in D with a range of 30'. Slight disturbance continued throughout 25th, H and V being below their normal values between approximately 4h and noon.

There was minor activity during most of the rest of the month, but the period 30d 6h to 3ld 2h was quiet.

AUGUST. - (Average Character Figure 0.65)

No disturbance worthy of description occurred during this month, though there was continuous minor activity over long periods. Slight disturbance took place from 19d 4h till 25d 9h and from 27d 12h till September 1d 6h. The quietest periods were: 2d 18h to 5d 10h, 14d 2h to 15d 4h and 16d 22h to 19d 2h. A small "sudden commencement" at 8d 22h 2m was followed by a slight increase of activity in D.

Aurora was seen from one or more places in Scotland on the evenings of August 12, 20 and 27.

SEPTEMBER. - (Average Character Figure 0.97)

There was no disturbance during the first nine days, the periods 1d 10h to 4d 8h and 8d 2h to 9d 4h being quiet. Disturbance developed on 10th, and became intense during the night of 11th-12th. On 11th, after small and rapid oscillations during the morning and afternoon, there was a sudden peak of 210v in H between 17h 48m and 18h 13m; this was accompanied by a small double peak in V, and immediately followed by a sharp drop of 22' in D. Thereafter H and V fell irregularly, and were below their undisturbed values from about 21h till 12d 7h; the depth of the trough in V was of the order of 200y from 22h till 6h, and there were three deep minima in H between the following approximate times: 23h 30m - 24h 0m; 12d 0h 10m - 1h 45m; 2h 25m - 3h 35m. Between 11d 20h 30m and 22h 35m D made several rapid oscillations within a range of some 50', D continued to fluctuate irregularly throughout the night; increased by 63' from its minimum shortly after 3h to its maximum two hours later, and fell by 32' in the next hour. After 12d 6h the disturbance died away, and was not renewed. Ranges for this disturbance: H 764y, D 62'9, V 501y.

From 13d 6h till 14d 10h and from 20d 14h till 23d 2h conditions were quiet, the intervening period being slightly disturbed.

Disturbance began in the early hours of 23rd. During the afternoon the maximum of H occurred at 15h 29m after a sharp rise of 140 γ and the maximum of D at 15h 36m in a peak 22' high. H remained high till soon after 18h, and the maximum of V occurred at 18h 29m. Both then fell rapidly, reaching minima shortly before 23h, and were low until 24d 6h. The minimum of D occurred at Oh 35m and was followed by a rise of 37' to a peak at 2h 13m. The ranges in this period were: H 545 γ , D 54'4; V 394 γ .

Disturbance was slight on 24th, but was renewed at 25d 2h, when there were small irregular dips in H and V, lasting till 4h 40m and about 6h respectively; D fluctuated through 37' from a minimum at 2h 20m to a maximum at 3h 45m. Considerable disturbance took place during 25th and 26th, though the ranges were not very large; this diminished in intensity after 26d 17h, but conditions did not become calm, and disturbance was renewed on the afternoon of 30th. After some irregular fluctuations, H and V began to fall at 19h, and reached minima at 23h 24m and 23h 25m respectively, the ranges from the afternoon maxima being 266y and 356y. In each case the minimum was followed by a rapid rise.

Aurora was seen from one or more places in Scotland on the evenings of September 2, 4, 6, 7, 15, 16, 18, 19, widely on 23 and 24 and from some places on 25, 26, 27 and 30.

OCTOBER. - (Average Character Figure 0.97)

A "sudden commencement" at 2d 17h 20m (-8γ , $+30\gamma$ in H, $-0^{\circ}2$, $+2^{\circ}1$ in D, -3γ , $+6\gamma$ in V) was followed by a slight increase of activity lasting till midnight. Conditions were then quiet until the end of 6th.

Agitation or minor disturbance was present almost continuously from 7d Oh until 20th, when disturbance increased in intensity after 10h. All three elements rose to maxima in the afternoon and fell to minima at about 21h. Dur-

ing the daylight hours of 21st there were continuous small movements. Between 16h and midnight D made several oscillations through ranges of about 30' and one dip of 38' between 17h 35m and 18h 55m. H and V did not rise to high maxima in the afternoon, but fell to minima soon after 23h, that of V being the absolute minimum for the storm. After this there were irregular fluctuations until 22d 6h, and the disturbance died away during the day. The ranges for 20th-22nd were: H 328y, D 66'3, V 393y.

There was a short quiet interval, and disturbance was renewed after a "sudden commencement" at 24d 6h 39m (+8\gamma, -29\gamma in H, -1'5, +5'3 in D, +2\gamma, -4\gamma in V) H immediately began to fall and D to rise, but movements were not at first large. At 11h 20m a rise began in V which amounted to 110\gamma at the end of half an hour; V remained at a high value until after its maximum, which occurred among a number of small and nearly equal peaks between 14h 30m and 16h 10m. H began to rise rapidly soon after 14h, reaching a peak some 350\gamma high at 14h 48m, and fell again after a smaller peak at 15h 35m, reaching a value slightly below normal at 16h 25m. Between 14h 20m and 15h 50m D oscillated rapidly, within a range of 27'. The ranges on 24th were: H 430\gamma, D 31'8, V 205\gamma.

There was a brief recurrence of disturbance on 25th, between 19h and 26d lh, and conditions became moderately quiet until, after a small "sudden commencement" at 27d 3h 46m, disturbance again broke out. At first there were only small and rapid oscillations, but the maxima of all elements occurred in peaks between 19h and 20h, that of H being very sharp. The night minimum values were not very low, but that of H, in a sharp dip at 2lh 47m, was followed by a rise of 324y to a very sharp peak at 22h 3m, almost simultaneous with a peak in V and a sharp dip in D. No further large movements took place, but slight disturbance continued until the end of the month.

Aurora was seen from one or more places in Scotland on the evenings of October 1, 4, 10, 20-22, 24-27, 30 and 31.

NOVEMBER .- (Average Character Figure 0.53).

There was no large disturbance this month. The following periods were the most disturbed: 2d 16h to 3d 4h; 5d 15h to 6d 12h; 1ld 18h to 15d 4h; 27d 15h - 2lh. The largest ranges in any one of these periods were those of the night 12th-13th, viz., 172y in H, 48'2 in D, 308y in V.

On 27th there were small irregular humps in H and V during the evening, but the disturbance died out after 21h, and conditions immediately became quiet.

The quietest periods were: 10d 2h to 11d 7h; 15d 9h to 18d 10h (the first 24 hours very quiet); 21d 18h to 27d 12h.

Aurora was seen from one or more places in Scotland on the evenings of November 2, 6, 12, 14, 16, 18, 27, 29 and 30.

DECEMBER. - (Average Character Figure 0.81)

There was no large disturbance this month. The most disturbed periods were: 14d 14h to 15d 8h and 25d 18h to 28d 4h. Conditions were quiet from

4d 6h to 7d 8h; moderately quiet from 19d 2h and very quiet from 22d 2h till 24d 19h. Some activity or slight disturbance was present during almost all the rest of the month.

Aurora was seen from one or more places in Scotland on the evenings of December 4, 5, 9, 13, 14, 16, 19 and 28.

Annual Values:- Character Frequency. 84 202 79

Mean Character Figure 0.99 (365 days)

Duration of Megative pot. grad: Total 680.6 hrs.

No. of days 362

Mean 1.80

Explanatory Note:- The electrical character of the day is indicated by the figures 0, 1, or 2, according to the character of the trace of the electrograph as regards negative potential gradient. The explanation of these symbols is as follows:-

- 0, denotes a day during which from midnight to midnight no negative potential was recorded.
 - 1, denotes a day with excursions to the negative not amounting in the aggregate to more than three hours.
 - 2, denotes negative potential extending in the aggregate over three hours or more.
- a, denotes that within the 24 periods of 60 minutes for which an estimate of the mean potential gradient has to be made in the process of tabulation, there was in no case a range of potential gradient in the open exceeding 1000 volts.
- b, denotes that a range of potential gradient in the open exceeding 1,000 volts was reached in at least one but in fewer than six of the 24 hourly periods referred to above.
- c, denotes that a range of 1,000 volts or more occurred in at least six of the 24 hourly periods.

In the interests of brevity there have been omitted from the table above all dates on which the sky throughout the evening remained completely overcast and on which, therefore, no opportunity arose of determining whether or not aurora occurred. The nights on which aurora was actually seen are indicated by the symbol M. The nights on which aurora was not seen despite at least an occasional interval of more or less clear sky, are indicated by the symbol .; in the latter case also, remarks on the weather are added to assist the reader in judging how far the fact of no observation of surora may be taken as indicating that there was not actual aurora. The letters a, b, c, have the following significance.

ing significance.

a = Conditions favourable for seeing aurora.

b = Unfavourable for faint aurora (monlight, mist, cist, etc.)

but not such as to mask bright aurora.

c = Cloudy, but aurora not seen in clear intervals.

ca,cb= have been used for "cloudy, with conditions a or b

in the intervals."

Changing conditions have been indicated by a hyphen,

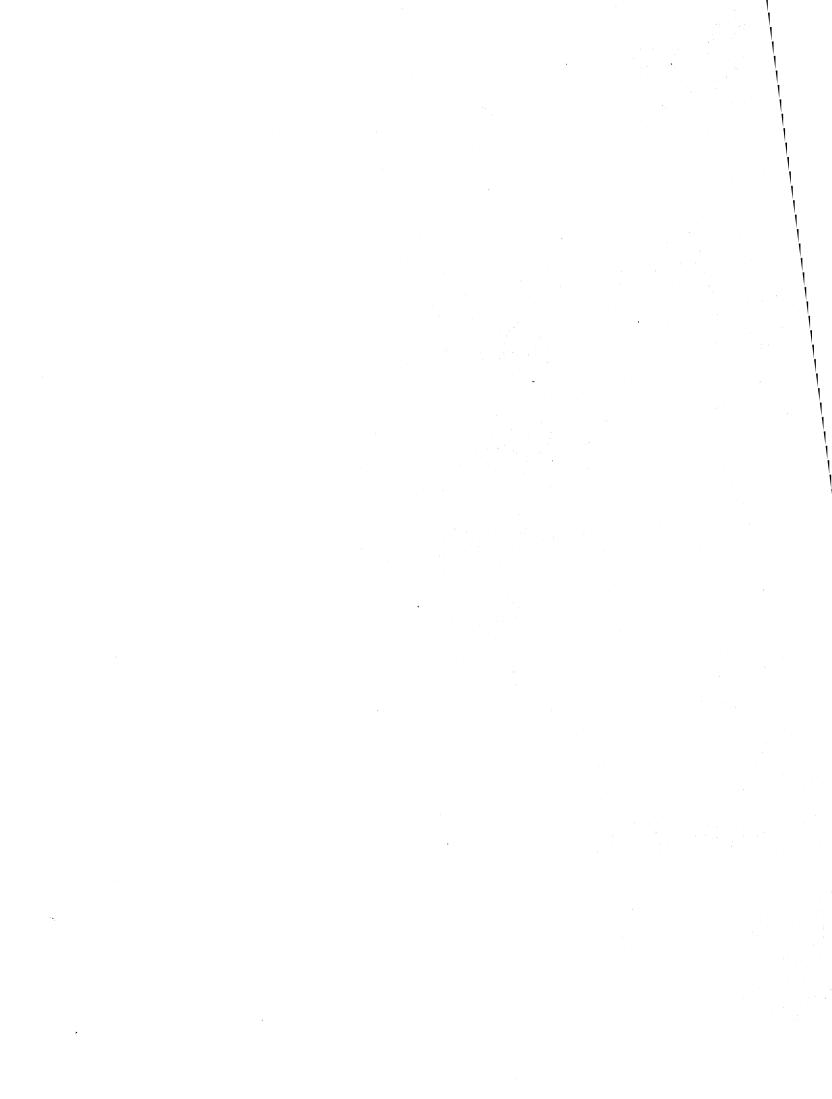

e.g., a-c.

A full description is available of the auroral phenomena observed.

INTRODUCTION

SITE

The Observatory, which was established in 1868 is housed in the top floor of the Cromwell Tower of King's College in Old Aberdeen. The College lies on a plain gradually rising from the sea from which it is distant 1 mile (1.6 km.) There are no serious irregularities of surface in the vicinity excepting the two river valleys of the Don and the Dee. To the north at a distance of about 1 km. the Don flows eastwards to the sea; flows into the sea at a distance of about 3 km. to the south-east of the Col-Between the College and the sea is a golf course covered for the most part with grass, but during the last four years the town has been gradually expanding to the north-eastward of the Observatory; this growth was very rapid during 1933 and 1934 with the result that there now exists an inhabited area stretching almost half a mile (1km.) between the Observatory and the sea in the north-east quadrant. Westwards is the High Street of the Old Town and beyond this is another street. Further west grass pasture extends for about 1 km. To the southward and south-westward lies the main area of the City of Aberdeen.

Because of the aforementioned developments and of their possible further extension under new town-planning schemes, it became necessary in 1933 to seek another site for the Dines Pressure Tube Anemometer situated at Ladymill, east of the Observatory. This instrument was therefore dismantled, and a new pressure tube instrument, with one-inch pipes, was erected at a new site on the Glebe situated to the north-west of the Observatory, and at a distance of about 350 metres therefrom. To this site were also removed the Stevenson screen, rain-gauges, etc. from the Athletic Ground site north-east of the Observatory, because the surroundings of this latter site were likewise becoming unsatisfactory. All the outdoor instruments are therefore now grouped together. The change of site was made on 31st March 1933.

New plans and photographs appear in the present volume. The changes that have occurred in the site and in the disposition of the instruments since 1928 can be ascertained by comparing these with the corresponding details in the 1928 volume.

Change of value adopted for height of Station above Mean Sea Level .- The numerous changes of late years call for some remarks upon the adopted values for the heights of station and instruments above M.S.L. Prior to 1st January, 1925, the value for the station level was 14.0m., and that for the height of the barometer cistern was 26.8 m. As from 1st January 1925, however, following a careful redetermination of these heights the values were altered to 13.4 m. for the Station level and 26.0 m. for the height of the barometer cistern. The change of site of the rain-gauge enclosure in June 1928 altered the value for the station level to 11.4 m. at which figure it remained until 31st March 1933, when the removal of instruments to the Glebe again altered it to 24.1 m. as from 1st April 1933. The actual heights of the barometer cistern, of the north-wall screen thermometer bulbs, and of the Robinson Cup Anemograph and the Campbell-Stokes Sunshine recorder have remained unaltered throughout.

METEOROLOGY

The elements dealt with in the following tables are: Atmospheric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, earth temperature and minimum temperature on the grass, together with a diary of cloud and weather.

The instruments from which values of the above elements have been obtained and the methods of tabulating the records are described in the General Introduction to this volume. The following additional information refers especially to Aberdeen.

Pressure and Temperature. The photo-barograph, standard Fortin Barometer and thermograph are housed in the Observatory room. The pressure scale value of the photo-barogram is 1 mb. = 1.18 mm. on the paper, when the paper is at normal atmospheric humidity. In similar circumstances the time scale is 1 hour = 9.3 mm. The records of the photo-barograph are standardized by means of control readings taken from the standard barometer. Up to the end of 1928 this instrument was Fortin Standard Barometer M.O. 273, but from the 1st January, 1929, it was replaced by Fortin Standard Barometer M.O. 1149. The N.P.L. certificate of this latter barometer shows a standard temperature varying from 286° A at 1,050 mb. to 287° A at 910 mb; corresponding corrections have been applied to the control readings.

The recording thermometers are placed in the North-wall screen already referred to. The scale value of the wet bulb thermograph record is 1° absolute = 3.20 millimetres on the paper; for the dry bulb thermograph the scale value varies slightly with the temperature, but is approximately 1° absolute = 3.4 millimetres. The time scale is 1 hour = 9.23 millimetres. Reading of the photo-thermograms is done by means of glass measuring scales, the records being standardized by control readings from Standard Thermometers M. O. 1698 (dry bulb) and M.O. 1697 (wet bulb). These thermometers have corrections, varying at different parts of the scale, of between -0.1° A and +0.2°A; these corrections have been applied to the control readings. The heights of the barometer cisters and of the bulbs of the thermometers are given at the top of the appropriate tables.

It may be here emphasised that the bulbs of the thermometers in the North-wall screen are at the considerable height of 12.5 metres above the ground, and that readings from these thermometers are exclusively used for this publication (except as noted below under Humidity) and for the corresponding summaries printed in the Monthly Weather Report.*

Rainfall. The recording instrument in use is Beckley Rain-gauge No. 2 with an area of 101·1 square inches (653 cm.²). The procedure adopted in tabulating the records is similar to that described in the General Introduction and calls for no comment. Control was by check gauge M.O.266 during the year 1935.

Humidity.- On those occasions when the temperature of the wet bulb has been 273°A or under, the relative humidity has been obtained from the records of a hair hygrograph. The instrument is accommodated in the North-Wall Screen beside the bulbs of the photo-thermograph and the standard thermometers. Prior to 16th September 1934 this had not been the case. Until 31st March 1933 the hair hygrograph was placed in the Stevenson screen at the Athletic Ground site, where its height was 13°2 m. below that of the thermometer bulbs in the North-wall screen, and from 1st April 1933 to 15th September 1934 the hygrograph was accommodated in the Stevenson screen at the Glebe site, and was at a height 0°5 m. below the level of the thermometer bulbs in the North-wall screen.

Sunshine. The sunshine recorder (Campbell-Stokes type) is exposed on the small circular tower on the Observatory roof on which the Robinson Cup Anemograph is erected. It is rigidly held by lead flaps soldered to the lead roof. The actual diameter of the sunshine sphere is 4.02 inches, and the focal length 2.97 inches, these figures being slightly in excess of the standard values (diameter 4.00 ± 0.5 inches, focal length 2.95 ± 0.1 inches). The exposure is excellent; the only obstruction is a flagpole to the east, of angular diameter about 1°, which may obstruct 0.1 hr. record about 7h. between April and September. This loss has been allowed for, whenever practicable, in tabulating records. In computing the percentage duration of sunshine the actual possible values for each day of the year 1935 have been employed, a procedure similar to that adopted from 1926 onwards.

Wind Speed and Direction. It was decided that as from 1st January 1935, the values for all the tables dealing with wind speed and direction should be tabulated from the records of the Dines Pressure Tube Anemometer which is installed on the Glebe site, instead of, as formerly, from the records of the Cup Anemometer situated on the Observatory Tower. No adjustments have been made to the values recorded by the Pressure Tube Anemometer to allow for the effect of the unsatisfactory exposure of the instrument to winds coming from directions between 35° and 115°. In this sector the "effective height" of the anemometer vane above ground is only 8 feet as compared with the standard "effective height" of 33 feet.

In consequence of this new procedure the values of wind speed shown in the Tables for 1935 are not directly comparable with those shown in previous volumes of the Year Book and derived in the manner described on p.90 of the volume for 1934.

^{*}The temperatures for Aberdeen published in the "Daily Weather Report" and summaries from them given in the "Weekly Weather Report" are from different thermometers, viz., those in the Stevenson Screen, with their bulbs only 1.3 metres above the ground.

On the very few occasions when records from the Dines Pressure Tube Anemometer have been defective, the required values have been taken directly from the records of the Cup Anemometer without any adjustment for exposure.

<u>Farth Temperature.</u> Readings have been made at 9h. G.M.T. of earth temperature at nominal depths of one foot and four feet below the surface of the grass.

The thermometers and the method of exposure are of the standard type described in the "Meteorological Observer's Handbook". The depths of the thermometer bulbs below the grass-covered surface of the ground are 30 and 122 cm.

The data published in the "Observatories Year Book" 1922 -1930 were the readings of an instrument with its bulb at a depth of 124 cm. This instrument, a description of which is given in the Year Book for 1930, p.86, was of unorthodox type, and was situated in the College Gardens until the end of June 1928. It was then removed to the anemometer enclosure, Ladymill. From 1st January, 1930, the published data refer to new instruments of standard type which were in the anemometer enclosure at Ladymill until 8th June, 1932. They were then removed to the Athletic Ground site, where they were installed near the screen and rain-gauges. The results of a comparison between the new and old instruments at a nominal depth of 122 cm. at the Ladymill site will be found in the Year Book for 1931, pp. 86-87.

For the period 18th June, 1932, to 25th March, 1933, comparative readings are available from the new 122 cm. thermometer at the Athletic ground and the old instrument at Ladymill. The results indicate that at 122 cm. depth the Athletic Ground is about 1.50A to 20A warmer than Ladymill during June, July and August, and about 10A colder in November, December, January and February. Similar comparative observations are not available for the College Gardens site, but some idea of the differences between that site and Ladymill can be obtained by comparing the readings at Ladymill during the four years, June 1928 to May 1932, with those obtained for many years prior to June 1928, at the College Gardens. These indicate that Ladymill is warmer than the College Gardens from September to April and colder from May to August, the maximum differences being approximately +2°A and -1°A. The continuity of the earth temperature readings has thus been seriously affected by the changes of site. The thermometers were transferred at the end of March 1933 to the Glebe site, thus introducing another discontinuity the effect of which cannot yet be estimated.

Minimum Temperature on the Grass.— The grass minimum thermometer is exposed in the enclosure on two wire pegs about 4 cm. above the grass. It is set at 18h and read at 7h, the reading being entered to the day of observation. Up to 8th October, 1935, the instrument in use was the spirit-minimum thermometer M.O. 17944/27, whose readings require no correction. On the 9th October 1935 there was brought into use a new Glycol-ether Minimum thermometer M.O. 60385/35 which has a correction of -0.20F at 120F, -0.10F at 320F, and 0.00F. at 520F.

Cloud. - From the 1st January, 1931, the recording of cloud-forms at Aberdeen has been in conformity with the definitions laid down in "Instructions for Meteorological Telegraphy" M.O. 191/1 (1930.

<u>Visibility.-</u> In the subjoined table there is given a list of the objects

used for the determination of the degree of visibility, together with their distances and bearings from the observation-point, which may be taken as the roof of the Observatory tower, the N.E. corner thereof being used for the nearer objects.

The range of visibility from the Observatory is somewhat limited by the high ground surrounding the city. From S.E. through S.to N. the distance of the visible horizon is between 2 and 4 miles (4 to 7km.), but in the N.W. a higher hill, at a distance of 5 miles (8.5 km.), rises above the nearer ridges. To the N.N.E. however there is a clear view of the coastline as far as Cruden Scaurs, where the coast consists of cliffs over 100 feet high, and is nearly 19 miles (30 km.) distant. From N.N.E. to S.E. there is only the sea-line as horizon, which from the height of the Observatory tower is about 10 miles (16 km.) distant.

Definite objects exist at standard distances from A to H, but from I to M there are no definite objects, though there are adequate identification marks for K and L. Owing, however, to these marks being on the sea-coast, and to the generally clearer visibility to the seaward side of the Observatory, it has been deemed advisable to employ small letter entries for all visibility distances that are not definitely landward estimates. The distances I and J are based upon estimates between other available distances. 21h observations of weather and visibility are made as a rule not actually at the Observatory, but in the neighbourhood within a radius of one or two miles. Apart from that it has to be remarked that, during darkness when the usual fixed objects cannot be seen, the estimates depend upon personal judgment, and upon the degree of obscuration, and alteration in the colour, of the surrounding lights of the town.

REVIEW OF METEOROLOGICAL RESULTS

Pressure: The mean pressure for the year 1935 was about 2 mb. below the normal value. Only the months of July and August showed anything like a close approach to their normal values, whereas excesses of 8 to 10 mb. were recorded in January, March and May, and deficits of over 9 mb.in February, September and October. The largest departure was recorded in February, whose mean pressure of 998.4 mb. was 12.2 mb. below the normal. February was the month with the lowest mean pressure and May that of highest mean pressure. The absolute extremes of pressure, at Mean Sea Level, for the year were 1046.0 mb. on 9th March and 959.5 mb. on 19th October: giving a range for the year of 86.5 mb. Very great ranges of pressure were shown in several individual months; December showed a range of about 80 mb., January 73 mb., and February 63 mb. The most striking movement of pressure occurred between the 18th and 20th October, when the pressure fell nearly 57 mb. in 22 hours, and rose subsequently over 51 mb. in 37 hours.

The results of the harmonic analysis of the diurnal inequalities of pressure for the months, seasons and year are set out in the accompanying Table. The unit employed is ·Ol mb. The phase-angles are reduced, as previously, to Local Mean Time. The average values of the various Coefficients for the period 1871-1926, computed by Dr. A. Crichton Mitchell* are given for comparison. Dr. Mitchell gave the phase angles in Local Apparent Time and in earlier volumes of the Year Book they were so quoted; the angles have now however been converted to Local Mean Time, and the amplitudes have been rounded off to ·Ol mb.

^{*} Diurnal Variation of Pressure and Temperature at Aberdeen, 1871-1926, by A. Crichton Mitchell D.Sc., Q.J.R. Met. Soc. 1929, p.197.

NOTE.-"Winter" comprises the four months January, February, November, December, "Equinox" the months, March, April, September, October; and "Summer" May to August.

The variations in both the phase-angle and the amplitude of the 24-hour term are very considerable this year. The amplitude is very small in October, and large in February and April.

The 12-hour term also shows greater variation than is usual in both phase-angle and amplitude. The equinoctial maxima in amplitude are well marked, as also is the summer minimum, and they occur in the usual months.

This year the 8-hour term departs considerably from its usual course. The summer maximum of amplitude is suppressed and the equinoctial minima do not appear. The reversal of phase-angle occurs as usual but in spring its incidence is delayed for a month.

The 6-hour term shows close agreement with the normal in its amplitude variations and in the seasonal changes of phase-angle, though there is a tendency for the maximum to occur somewhat later than usual in the first half of the year, and rather earlier than usual in the latter half of the year.

Temperature: The mean temperature for the year 1935 was about 0.50A above the normal, but the departures of the individual months from their normal values, were, in all cases except one, less than 1.50A. The exception is March which showed an excess of about 20A. March and August were the months with greatest excess of temperature, while December showed the largest deficit. The highest temperature of the year was 297.90A on 23rd July, and the lowest was 266.50A on 24th December.

Relative Humidity: Over the year there was an excess of 0.5 per cent in the relative humidity and in five of the individual months the departure from normal was 3 per cent or more. June showed an excess of 6 per cent, April

and December excesses of 5 per cent. September and October showed deficits of 3 per cent, despite the fact that both these months had excess rainfall, September, in fact, having nearly twice its normal amount.

Rainfall:- The precipitation in 1935 was 156 mm. above its average value, the total amount recorded being 904 mm. Four very wet months, April, June, September and November, with excesses of 57 mm., 64 mm., 52 mm., and 33 mm. respectively, contributed to this increase over the normal amount and no correspondingly large deficit was shown by any other month, the driest month being May whose fall of 41 mm. was only 18 mm. below the normal value. It is a curious coincidence that the falls recorded in the above mentioned wet months were of almost the same amounts, 105 mm., 107 mm., 108 mm. and 108 mm. respectively.

Sunshine:- The sunshine recorded during 1935 was about 1 per cent below normal. The largest departures occurred in July, whose value of 42 per cent of the possible was 13 per cent in excess of the normal value, April, whose 25 per cent of the possible was 10 per cent below normal, and June, whose 26 per cent of the possible showed a deficit of 8 per cent. The remaining nine months were all within 5 per cent of their normal values. On only 9 days of the year did the recorded sunshine reach or exceed 80 per cent of the possible, the highest value, 85 per cent of the possible, occurring on 24th May and 31st October. The brightest day of the year was 24th May, when 14.5 hours were recorded, and on only two other occasions, 29th June and 11th July, did the day's sunshine reach or exceed 14 hours.

<u>Wind Speed:-</u> This year the mean value of wind-speed was only 3.6 m/s as compared with 4.6 m/s last year, but this decrease is due almost entirely to the adoption of the new basis of tabulation described on p.92 of this Introduction.

April was the month with the highest mean wind speed, the value recorded being 4.4 m/s, while August with 2.5 m/s had the lowest mean wind speed. The highest hourly speed recorded during the year was 17.1 m/s on 14th February.

Minimum Temperature on the Grass: - On 77 occasions during the year ground frost (less than 272.20A) was recorded. The months of greatest frequency were February, November and December. From June to September inclusive, no occasion of ground frost was recorded. The lowest temperature "on the grass" was 263.10A on 26th February.

Temperature in the Ground: The annual mean temperature in the ground at a depth of 1 foot was 281.6°A, and that at 4 feet was 281.7°A. These compare with the annual mean temperature of the air of 281.35°A. At a depth of 1 foot the lowest mean monthly value was 276.6°A in February and the highest 288.5°A in August. The extremes values during the year were 289.8°A on 8th August and 275.6°A on 27th February. Corresponding values at a depth of 4 feet were 277.8°A in February and 287.0°A in August, with extremes of 287.3°A on 29th August and 277.5°A on 2nd March.

Cloud and Weather: The annual mean cloud amount was 7.0 tenths. The cloudiest month was April with a mean cloud amount of 7.7 and the least cloudy months were July and December, both with a mean cloud amount of 6.2.

Aurora: - During the year 1935 Aurora was recorded on nine occasions, two in

the earlier half of the year and seven in the later half. Dates of occurrence are given in the General Auroral Table.

General Remarks: - As a whole the year was wet and rather duller than normal, though there was a slight excess of temperature. The outstanding feature was the raininess of the usually relatively dry months of April, June and September. Other features of interest were the relatively high percentage of sunshine in July and low percentages in April and June.

69. ABERDEEN: H_b (height of barometer cistern above M.S.L.) = 26.0 metres

NOTE. - When pressure exceeds 1000 mb. the leading figure 1 is not printed, i.e., 1005.6 is written 005.6. This rule does not, however, apply to monthly means.

PRESSURE AT STATION LEVEL AND AT SEA LEVEL. ANNUAL MEANS FROM HOURLY VALUES. From readings in millibars at exact hours, Greenwich Mean Time.

81. ABERDEEN: $H_b = 26.0$ metres.

NOTES ON RAINFALL

114. ABERDEEN

1935

Notable Falls of the Year. The only heavy fall of rain was 55 mm. on June 5th -8th; of this, 51 mm. fell on the 5th. Falls exceeding 25 mm. occurred as follows: -26 mm. on April 16th, followed by a further 9 mm. on the 17th; 29 mm. on September 17th of which amount 17 mm. fell in 4 hrs.; 31 mm. in 12 hrs. on the 3rd and 4th October; 25 mm. on November 17th followed by a further 11 mm. on the 18th.

Falls of 5 mm. were recorded in 6 mins. on July 17th, in 9 mins.on August 8th, in 15 mins. on September 2nd and in 18 mins. on June 16th. The shortest durations of falls of 10 mm. were lhr 6 mins. on July 17th, lhr. 18mins. on September 17th and in lhr. 38mins. on August 8th.

Dry Periods.

(Periods of 7 days or over with no rainfall or with trifling amounts.)

Jan. 17 - 23 No rain for 7 days. Mar. 6 - 17 May 1 - 11 May 20 - June 2 July 30 - Aug. 7 " " 12 " " " 11 "

There were no periods of "absolute drought" or of "partial drought" though the period of May 20 - June 2 approximates closely to the former.

Wet Periods.

There was one "rain spell" - from Mar. 28 - Apl. 11, but no "wet spell" was recorded.

Rate of Rainfall. (Jardi Recorder) The highest instantaneous rate of rainfall was 125 mm./hr. at 12h. 5m. on July 17th. On this same day rates exceeding 70 mm./hr were recorded on two other occasions during the very heavy showers which yielded in all 17 mm. of rain. Maxima exceeding 50 mm./hr. were recorded on August 8th , September 2nd ,September 25th , October 30th and November 10th.

RAINFALL Amounts in millimetres, for periods of sixty minutes between the exact hours, Greenwich Mean Time

115. ABERDEEN: Hr (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + hr (height of receiving surface above ground) = 24·1 metres + 0·6 metres

WIND: DIRECTION AND SPEED

Direction expressed in degrees from North (E = 90°, S = 180°, W = 270°, W = 360°). Speed in metres per second

143. ABERDEEN: Dines Pressure Tube Anemometer from Jan. 1935. Ha (height of anemometer above M.S.L.) = height of ground above

Hotes.- (1) The initial 2 or 3 of the readings is omitted, i.e., 275.0 degrees absolute is written 75.0.

(2) The minimum "on the grass" refers to the interval from 18h on the previous day to 7h on the day to which it is entered.

INTRODUCTION

HISTORICAL

Early in the twentieth century the increasing artificial magnetic disturbance at Kew Observatory, Richmond, due to the westward extension of the electric tramway system from London, made desirable the establishment of a magnetic observatory in a locality unlikely to be affected, at least for a number of years, by electric power or traction system. A committee of the Royal Society of London selected a site in the parish of Eskdalemuir, Dumfries-shire, for the new observatory. The nearest towns or industrial centres are Langholm and Lockerbie, distant approximately 16 and 18 miles (26 and 29 km.) by road, and there is no point of railroad within 9 miles (14km.) of the Observatory. Installation of the instrumental apparatus commenced in the summer of 1908, the Observatory at that time forming a part of the then recently established National Physical Laboratory.

Although the Observatory was established primarily in the interests of the study of terrestrial magnetism the field of geophysical work undertaken has been considerably wider and has included, almost from the beginning, meteorology, atmospheric electricity (mainly atmospheric potential gradient), and seismology. In the earliest years Milne, Wiechert, Omori, and Galitzin seismographs were in operation at Eskdalemuir, but seismological observations ceased in October, 1925, when the three-component installation of Galitzin seismographs was transferred to Kew Observatory. In 1910, when the majority of the various initial difficulties had been overcome, Eskdalemuir passed from the control of the National Physical Laboratory to that of the Meteorological Office. In consequence of this change the meteorological work assumed increased importance, and from the beginning of 1914 the Observatory has served as a telegraphic reporting station of the Meteorological Office.

Summaries of the results of observations made in 1909-10 were published in the Report of the Observatory Department of the National Physical Labora-

tory, 1909-10. The results for subsequent years are included in the publications mentioned in the Preface to the present volume.

SITE

Eskdalemuir Observatory, some $3\frac{1}{2}$ miles $(5\frac{1}{2}$ km.) north-north-west of Eskdalemuir Parish Church in the county of Dumfries-shire, is situated on a rising shoulder of moorland which is bounded on the east by the road leading north to Ettrick and Selkirk, on the west by the small Davington Burn, and at the southern extremity by the small hamlet of Davington.

The hillside in the immediate vicinity of the Observatory slopes generally from the north-west to south-east. The mean height above sea level of the Observatory site is about 800 feet (244 metres). Cassock Hill, slightly more than a mile distant to the north-west is 1,205 feet (367 metres), while the bench mark at Davington School, $\frac{1}{4}$ mile (0.4 km.) to south-east, is 699 feet (213 metres) above M.S.L. To the east the ground slopes fairly rapidly to the valley bottom, the level of the Ettrick road at a point about $\frac{1}{4}$ mile (0.4 km.) east of the underground magnet house being 682 feet (208 metres). The River White Esk is rather less than $\frac{1}{2}$ mile (0.8 km.) to the east. Immediately beyond the river, and almost due east of the Observatory, Dumfedling Hill rises to a height of nearly 1,200 feet (366 metres) Some 4 or 5 miles (8 km.) to the north is a high ridge, following approximately the boundary between Dumfries-shire and Selkirkshire, the highest point of which is Ettrick Pen (north-north-west) 2,269 feet (698 metres) Rather more than half a mile (0.8 km.) to the west, and beabove M.S.L. yond Davington Burn, the ground rises to 1,040 feet (317 m.), and reaches nearly 1,200 feet (366 m.) half a mile (0.8 km.) further on. To the south and south-south-east the Observatory commands a view of the White Esk Valley as far as Hart Manor, 4 miles $(6\frac{1}{2} \text{ km.})$ distant, and beyond that the upper slope of Cauldkine Hill, about 10 miles (16 km.) distant, is visible. surrounding country is bare and wild and there are but few trees to relieve the monotony of the grass-covered hills and moorland.

Within the Observatory grounds the soil is peaty and in many places is more or less boggy at all seasons. Some two feet, or less, below the surface a clay-like substance containing soft rock is encountered. The Local geological formation is described as "rock of the Tarannon Llandovery series traversed by igneous dykes."

The general features of the immediate surroundings and the lay-out of the buildings may be seen from the accompanying photographs, plan and map.

The following brief descriptive notes serve as an index to the accompanying site plan (Fig.13).

There is a narrow belt of trees - chiefly conifers, with a few birch and rowans - around the greater part of the Observatory enclosure. These trees were planted shortly after the building of the Observatory and subsequently. They are largest on the southern side.

(1) & (2) are two double-walled wooden huts in which absolute observations of the magnetic elements are made. The space between the inner and outer wooden shells is packed with non-conducting material. Lighting is provided by windows in the north sides and by skylights.

- (3) is the underground magnetograph house, constructed throughout of nonmagnetic material. Within the outer shell of stone and concrete, and separated therefrom and from each other by corridors and vaultings, are two similar rooms of which the approximate internal dimensions are:-Length, 25 feet (7.6 m.); width, 20 feet (6.1 m.); height, 10 feet (3.0 m.). of the rooms are just below the undisturbed level of the surrounding ground. The roof portion of the outer containing shell is covered with a thick layer of earth, thus forming the mound shown in Fig.14. The super-structure which is visible in the photograph is part of the ventilation system. room contains the standard magnetographs and the photographic barometer. Other magnetographs have been set up from time to time in the west room. Acetylene gas is chiefly used as illuminant.
- (4) is the Beckley self-recording rain-gauge, and (5) the standard 8 inch rain-gauge; each is surrounded by a low wall or dyke of turf.
- (6) is an auxiliary 8 inch rain-gauge but is not artificially screened.

(7) is a snow-gauge of the Hellman pattern, made by Fuess.

(8) is the Campbell-Stokes sunshine recorder on white of by the off the weakled of the weakled of

- (9) is a concrete pillar, 4 feet high, on which a pilot-balloon theodolite may be mounted. The pillar is surrounded by a wooden seat of convenient dimensions.
- (10) is the pit from which observations of the electric potential 1 metre above the surface of the ground are made. The dimensions of the brick-lined pit are 4 feet (1.2 m.) by 3 feet (0.9 m.) by 3 feet. which consists of a fixed and a hinged portion is covered with zinc, is provided with a small glass window, and is almost flush with the level of the approximately circular lawn indicated on the plan by the dotted circle.
- (11) is a stone pillar formerly used as a support for an aspiration apparatus but latterly used to support a Besson Comb nephoscope.
- (12) is a large louvred hut which contains the standard dry and wet bulb thermometers, the photographic and pen thermographs, and the maximum and minimum thermometers. The hut, of which the general features may be seen on reference to Fig. 14 is painted white inside and out. Until 1925, when electric light was introduced, acetylene gas was the illuminant for the photographic thermograph.
- (13) marks the position in which the grass minimum thermometer is exposed between 18h and 7h G.M.T.
- (14) & (15) are earth thermometers, 1 foot (0.3 m.) and 4 feet (1.2 m.)below ground level respectively.
- (16) is an auxiliary screen in which a hair hygrograph was exposed until June 15, 1928.
- (17) indicates the position of the mast of the Dines Pressure Tube Anemometer and (18) the position of the jet of the Kelvin water-dropper electrograph. Villam Callette
- (19) is a Jardi rate of rainfall recorder. It is installed in a pit six feet (1.8 m.) deep and screened by a low dyke of turf

- 0
- (A) is the main building two-storied and containing offices, workshop, laboratory, seismograph and photographic rooms.
 - (B) & (C) are residences (Schuster House and Rayleigh House, respectively)
- (D) & (E) are residences (Glazebrook House and Shaw House, respectively), which were erected in 1927-8.
- (a) is a water reservoir, from which water is distributed to the various buildings. The reservoir is fed from a spring on Cassock Hill by means of a pipe line.
 - (b) is a tennis court.
 - (c) is the acetylene gas generating house.
- (d) is a block containing the garage, the electric lighting generating set and the accumulator batteries. The electric lighting equipment, which was installed in 1924, provides for continuous illumination for photographic recording instruments in (3), (12) and (A) and for occasional general lighting in (A), (c) and (d). The voltage on the lighting circuits is restricted to 8 volts. Connection between the battery room in (d) and buildings (12) and (A) is by underground cable which is insulated, lead covered and armoured, and between (3) and (A) by insulated cable carried just above ground level. All precautions have been taken to guard against leakage of current to earth.
 - (e) is a workmen's bothy and (f) is a small greenhouse.

METEOROLOGY

The elements dealt with in the following tables are: Atmospheric pressure, air temperature, humidity, rainfall, sunshine, solar radiation, wind speed and direction, earth temperature and minimum temperature on the grass. There is also a diary of cloud and weather.

Notes on Instruments

Brief descriptions of the recording instruments and of the methods of tabulating the records, with notes on the information contained in the Tables, are given in the General Introduction to the Tables. The following particulars, which refer specially to Eskdalemuir, are to be regarded as amplifying the information contained therein. References to full accounts of other instruments used at Eskdalemuir appear below.

<u>Pressure.-</u> The Fortin Barometer, which after repair was re-introduced as standard in January 1933 and superseded the standard Kew pattern barometer, was used throughout the year. The two barometers are close together in the north-west ground floor room, which has a small daily range of temperature.

The photographic mercurial barograph is situated in the east roof of the underground magnet house. The daily range of temperature to which the instrument is subject is normally less than 0.05°C., the annual range being about 4°C. The scale value of the records is 1 millimetre on the paper = 0.85 millibar, and the time scale is 9.1 millimetres on the paper = 1 hour.

As in former years, records of pressure were also obtained from (a) a Dines float barograph, and (b) a Richard barograph, pen recording, the records of which are changed weekly.

Temperature. The photographic thermograph and the standard mercurial thermometers, dry bulb and wet bulb, are situated in a wooden hut, provided with louvred sides and double roof, which is some 200 feet (60 m.) north-north-east of the main building. The installation is similar to that described on p.12, except that a special enclosure is provided inside the hut to accommodate the optical and photographic arrangements.

The scale values of the thermograph records are $1^{\circ}A$. = 3.064 mm. and 2.438 mm. on the paper for the dry and wet bulb records respectively, while the time scale is 1 hour = 9.250 mm.

Auxiliary records of temperature are obtained from one or more instruments of the bimetallic type described in the "Meteorological Observers' Handbook". These instruments are situated in the hut which contains the photographic thermograph.

<u>Humidity.-</u> In addition to the dry and wet bulb thermograph described above there is a Richard hair hygrograph which is situated in the louvred hut.

As is stated in the General Introduction, the records from this instrument are utilised when the wet bulb reading does not exceed 273°A. On the records obtained in 1935 a change of 10 per cent. in relative humidity is represented by about 0-8 centimetre, the time scale being 1 hour = 11-4 mm.

Rainfall.- The recording instrument is a Beckley self-registering raingauge, which is described on page 13. The time scale of the record is 1 hour = 9.24 millimetres on the paper and the rain scale has a magnification of 3.35. The instrument has been in use at Eskdalemuir since 1908 and was originally installed at Fort William in July, 1890.

The conical part of the gauge funnel is surrounded by a cylindrical copper casing lined with asbestos on the inner side and of diameter equal to that of the funnel, viz. 11.27 inches (28.6 cm.). Within the enclosure so formed is a gas jet, and a flame of suitable dimensions is maintained, as circumstances dictate, to melt snow which may be collected.

The gauge is surrounded by a circular turf wall or dyke, the top of which is on a level with the rim of the gauge; the external and internal diameters of the dyke being 11.5 feet (3.5 m.) and 7 feet (2 m.) respectively.

A standard 8-inch (20.3 cm.) rain-gauge is situated some 24.5feet (7.5m.) to the east of the Beckley gauge and is surrounded by a turf dyke of similar dimensions. Readings of amounts of rain received in the 8-inch gauge are made at 7h and 18h G.M.T. It is customary to adjust the indications of the recording gauge to agree with the readings of the standard check gauge.

Auxiliary autographic records of precipitation were obtained by means of a Hellman-Fuess snow-gauge which is situated in a pit 8 feet (2.4 m.) wide

Q.J.R. Meteor. Soc., Vol. LV, pp. 37-53, 1929

and almost due north of the 8-inch standard gauge, the pit being surrounded by a low wall of earth and turf, the top of the wall being approximately level with the rim of the gauge. The records so obtained are used only in the event of failure or uncertainty of the Beckley autographic record. Records of rate of rainfall are obtained by means of a "Jardi" rate of rainfall recorder situated in a pit similar to that containing the Hellman-Fuess snow gauge and situated to the eastwards of it; the rim of the gauge is approximately 2.5 feet (0.3 m.) above the surrounding low wall of earth and turf.

Sunshine. The record of sunshine is obtained from a Campbell-Stokes recorder described on p.ll.

The recorder is fixed on a stone pillar and has a reasonably free exposure, the chief obstacles being hills to east and west. The elevation of hills between 70° and 110° east of south varies from 2.5° to 5°, while between 50° and 135° west of south the high ground varies in elevation from 3° to 4.4°, being generally about 3.5°. As sunshine can be recorded when the sun is 3° above the horizon only in the most favourable circumstances, it appears that the loss of record occasioned by the neighbouring high ground is of relatively small extent and is confined mainly to a possible defect of record at the beginning of the day during a few weeks centred about the equinoxes.

Solar Radiation. Measurements of the intensity of radiation received from the sun by a surface which is normal to the line drawn from the instrument to the sun are effected by means of an Angstrom compensating pyrheliometer. The intensity of radiation is expressed in milliwatts per square centimetre (lmw per sq. cm. = 0.01435 gramme calorie per sq. cm. per minute). In addition, the value of sec Z is given where Z in the zenith distance of the sun. This affords an indication of the mass of atmosphere which the solar radiation has had to penetrate before reaching the earth. Entries in the column headed "Sky" are intended to show the presence or absence of haze, mist or cloud in the direct path of the solar radiation recorded.

<u>Wind.- A Dines Pressure Tube Anemometer, furnished with direction recorder, is situated in the main building.</u> The vane-head is 15 metres above a tangent plane to the slope of the hillside and approximately 7 metres above the general level of the roof of the building.

In August 1933, the anemometer was replaced by another of similar pattern, except that the suction and pressure effects are now transmitted to the speed recorder by means of copper pipes of 2.5 cm. internal diameter, instead of by "compo" tube of 1.3 cm. internal diameter.

Apart from the surrounding hills, the exposure of the vane-head is tolerably free in all directions save to the west where at a distance of some 130 feet (40 m.) is a rather large building, of which the height is somewhat greater than that of the main building. With winds from nearly due west the direct-

¹For descriptions see "Astrophysical Journal", Vol IX, 1899; "Actes de la société royale des Sciences d'Upsal", 1893; also "Geophysical Memoirs", No. 21 (1923), Meteorological Office, London.

Following some structural repairs to the observatory building, the pyrheliometer was re-erected in an embrasure of the tower in June 1930.

ion records show markedly greater turbulence than with other winds.

Earth Temperature. Readings have been made at 9h G.M.T. of the earth temperature at nominal depths of one foot and four feet below the surface of the grass lawn a few yards south of the thermometer hut. The thermometers and the method of exposure are of the standard type described in the "Meteorological Observers' Handbook". The depths of the thermometer bulbs below the grass-covered surface of the ground are 30 cm. (1 foot) and 122cm. (4 feet). In December, 1930, two more thermometers, graduated in degrees absolute, were installed at 1 foot and 4 feet respectively alongside the other two thermometers graduated in degrees Fahrenheit, the former being retained as spares. The Fahrenheit pair were replaced as standards by the Absolute pair at the beginning of 1931.

Minimum Temperature on the Grass. The thermometer used for readings of grass minimum temperature is of the spirit type with index, and when exposed, between 18h and 7h G.M.T., is supported at a height of one or two inches (4cm) above close-cropped grass a few metres from the louvred thermometer hut.

Visibility.- The descriptions of the selected visibility objects, together with the distances and bearings from the point of observations, are given in the subjoined table. Auxiliary objects and guide criteria are given in brackets. Certain of the nearer objects may be identified by reference to the photographs and site plan. Unless otherwise stated, the distances and bearings are with reference to certain of the windows on the upper floor of the main building.

The situation of the Observatory and the nature of the immediate surroundings allow of only a very limited choice of objects. The objects A to D are situated mainly to the north, while the more distant objects are towards south to south-east, i.e., down valley. Four miles or so to the north of the Observatory the hills rise in places to rather more than 2,000 feet above sea level and at times visibility in this direction is distinctly less than towards south. On other occasions the hills to the north are visible but nearer objects down the valley are invisible owing to valley mist. With the exception of the cottage at Finglandsheil, and Cauldkine Hill, the objects more distant than D are below the level of the Observatory. There are no objects at distances which approximate sufficiently closely to the standard distances for objects H, J and K. When it is estimated that the range of visibility is such that objects at these standard distances would be visible the corresponding small letter entries are made in the Diary of Cloud and Weather. estimates of visibility in the dark depend largely on the judgment of the observer. There are no lights other than those in the Observatory buildings and in two cottages within a radius of one mile.

CORRECTIONS TO INSTRUMENTS IN USE IN 1935

The corrections to the instruments in use during 1935 are given below. In all cases the corrections are those given in the certificate of examination issued by the National Physical Laboratory. The corrections here given have been applied. The date on which each of the instruments mentioned was brought into use is given for purpose of reference.

NOTE ON THE REDUCTION OF BAROMETER READINGS

The Fortin barometer, M.O. 1716/27 by Casella, London, has been used as the standard since 1st January, 1929. Before this date a Kew pattern mercury barometer M.O. 1320 by J. Hicks, London, was the standard instrument from 16th December, 1913. The latter was re-introduced on July 14,1931 when the Fortin barometer developed a leak and was sent away for repair and remained in use until January 14, 1933; the repaired Fortin barometer was then re-introduced.

1. Reduction to Pressure at Station Level. The corrections for index error (including those for capacity and capillarity) as given in the N.P.L. certificates are reproduced above. The corrections for temperature for the barometer are those given in the "International Meteorological Tables" as appropriate to a Fortin barometer.

The corrections for the variation of gravity as obtained from the expression

 $g = 980.617 (1.00259 \cos 2\lambda) (1.5z/4E)$

where $\lambda = latitude$

z = height of the station

E = earth's radius

are as follows:-

2. Reduction to Mean Sea Level. The correction to reduce pressure at station level to pressure at sea level is calculated according to the usage of the "International Meteorological Tables" with certain minor modifications which are set out in "The Observatories' Year Book", 1928. In the same volume is given a copy of the Table actually in use.

NOTES ON THE METEOROLOGICAL SUMMARIES

The number of years for which meteorological results are available is insufficient as yet to yield a completely representative set of normal values. Although certain meteorological data are available for 1909 and 1910 it is only since 1911 that the reductions have been made in accordance with an approximately uniform plan. In the following notes the normal or average values referred to are for the period 1911 to 1930, unless otherwise stated.

Pressure.- As was the case throughout most of the British Isles the mean pressure for the year was below normal, the deficiency being 0.9 mb. In the months January, March, May, July and August the mean pressure was above normal, the greatest excess being in January viz. 12.9 mb.; in each of the other months it was below the average. The extreme instantaneous values recorded were 1014.1 mb. on January 18, and 939.2 mb. on December 1. The greatest and least mean daily values were 1013.3 mb. on January 18, and 943.2 mb. on December 1. The largest value of the range during a calendar day was 32.6 mb. on January 26. The mean value of the absolute daily range of pressure varied between 11.1 mb. in October, and 4.2 mb. in August. The annual mean value of the daily range was a little above normal.

Pressure. (Diurnal Variation):- In the mean diurnal inequality for each month there are two maxima, in the late forenoon and usually an hour or two before midnight, and two minima, in the early morning and afternoon. In all months, except January, February and November, the night maximum of the representative inequalities for the years1911-20 is the larger. In 1935 the principal maximum occurred in the late forenoon in January, March, July,MAY October and December. The principal minimum in the representative inequalities is in the afternoon except in February, March, August and November, but in 1935 the principal minimum falls in the early morning in February, April, August, September and November. Compared with the mean diurnal inequality for 1911-20(1), in 1935 the night crest is enhanced, while the early morning trough

^{(1) &}quot;On the Diurnal Variation of Atmospheric Pressure at Eskdalemuir and Castle O'er, Dumfries-shire," by A. Crichton Mitchell, D. Sc., "Quarterly Journal of the Royal Meteorological Society." Vol. L, No. 210, April, 1924.

is diminished.

The results of the harmonic analysis of the monthly and seasonal mean diurnal inequalities for 1935 are given in the accompanying table. For purposes of comparison the corresponding data $^{(1)}$ derived from the mean inequalities for the period 1911-20 are also given. In computing the Fourier coefficient for 1935 the unit employed was $\cdot 001$, mb. Although for 1935, as for recent years, the phase angles are given to the nearest 1° , this course is scarcely justified, at least for the third and fourth components, by the character of the data from which the harmonic coefficients for the months and seasons of a single year are computed. The phase angles a_1 etc, given in the table below refer to Local Mean Time, whereas in the corresponding tables for 1922 and 1923 the phase angles refer to Greenwich Mean Time.

As is usually the case the amplitude and phase of the 24-hour term fluctuate irregularly from month to month. The ratio of the mean of the twelve monthly values of \mathbf{c}_1 to the value of \mathbf{c}_1 for the year as a whole considerably exceeds unity. \mathbf{c}_1 is noticeably high for May and September. The value of \mathbf{c}_2 for the equinox, summer, winter and year differed little from normal. The variations in the 8-hour term from month to month is fairly normal, the amplitude being largest in winter months and least at the time of equinoctial phase transition.

HARMONIC COEFFICIENTS OF THE DIURNAL INEQUALITY OF ATMOSPHERIC PRESSURE ESKDALEMUIR, LONGITUDE 3° 12' W.

Values of c_n , a_n in the series c_n sin (15nt + a_n), t being Local Mean Time reckoned in hours from midnight.

NOTE.- "Winter" comprises the four months January, February, November, December. "Equinox" the months March, April, September, October.

[&]quot;Summer" the months May to August.

^{(1) &}quot;On the Diurnal Variation of Atmospheric Pressure at Eskdalemuir and Castle O'er, Dumfries-shire," by A. Crichton Mitchell, D.Sc., "Quarterly Journal of the Royal Meteorological Society," Vol. L, No. 210, April, 1924.

Temperature.— The mean temperature, 280·15°A. (44·9°F.), for the year 1935 is slightly above the normal value. The extreme temperatures recorded during the year were 299·7°A. (80·1°F.) on June 23 and 260·7°A. (9·9°F.) on December 23. December 23 with a mean daily temperature of 264·9°A. (17·4°F.) was also the coldest day of the year and June 23 with 293·6°A. (69·1°F.) was the hottest. The mean monthly temperatures in May, September, October and December were sub-normal, the mean in each of the other months being above the average, the greatest excess occurring in March (1·8°A.) and the greatest deficiency in December (2·1°A.). In addition the mean monthly temperature in March was the highest since records commenced for months of that name. The minimum temperature was 273·0°A. (32·0°F.), or less, on 88 days, 48 being in the first four months of the year. There were two "ice-days", i.e. days with maximum temperature below 273·0°A. (32·0°F.).

The values of the absolute range of temperature within a calendar month vary between 28.0°A. (50.4°F.) in June and 15.8°A. (28.4°F.) in December.

Humidity.- As is mentioned in the General Introduction, owing to a change in the hygrometric tables used, the results from 1926 onward are not strictly comparable with those of earlier years. Compared with the mean values for 1911-25 the chief departures of the values of mean relative humidity in 1934 are - 9 in May and + 6 in June. The mean relative humidity, 83.6 per cent. for the year, is slightly less than that for the years 1911-25, whilst the mean vapour pressure, 8.5 mb., is slightly greater than the mean for the years 1922-30. The extreme daily mean values of relative humidity and vapour pressure were 99.0 per cent. on June 21, 55.1 per cent on May 5, 19.3 mb. on June 23, 2.9 mb. on December 23. The lowest hourly reading of relative humidity was 27 per cent. on May 18.

Precipitation. 1935 was wetter than normal, the total amount of rainfall, 1523·1 mm. (59·95 in.), being 6-6 per cent. greater than the mean for the period 1911-30. The wettest months were February with 197·7mm.(7·78in.) and October with 263·7 mm. (10·38 in.). May with 29·4 mm. (1·16 in.) was very dry, being the driest May on record. The greatest amount recorded during a calendar day was 43·1 mm. (1·70 in.) on August 30. There were 135 days on which precipitation was nil or amounted to less than 0·2 mm. Precipitation amounting to 0·2 mm. or more was recorded on 230 days; to 1·0 mm. or more on 178 days; to 20·0 mm. or more on 12 days.

Snow or sleet fell on 53 days, but on no day from May 18 to October 10 inclusive. Observations of "snow lying" at 7h number 27, 18 of which were in December. There were no large falls of snow.

Sunshine. The year's total duration of bright sunshine, 1262.8 hr. represents 28 per cent. of the theoretically "possible" duration; whereas the average percentage of "possible" for the years 1911-30 is 26.9. As regards the percentage of "possible" May was the sunniest and October the least sunny month of 1935. In all, there were 86 days without sunshine, 14 of these being in January, and 13 in December, and 87 days with 50 per cent. or more of the "possible" sunshine. The day with the most sunshine was June 29, with 15.0 hr. July 30 with 14.6 hr. (91 per cent) represents the highest value of the percentage of "possible" sunshine. October (with 51.2 hr.) and December (with 59.9 hr.) were respectively the dullest and brightest months of their name, while May(with 267.7hr) was the sunniest month ever recorded.

Wind. The mean wind speed for the year, 4.7 m/s. (10.3 mi/hr.), was 0.4 m/s. less than the normal value. The individual monthly values differed respectively little from the normal monthly values, the mean speeds for January, November and December exhibiting the greatest relative deficiency and those for February and October the greatest excess. There were 35 hours of gale force (mean speed greater than 17.1 m/s.), 12 of them occurring in October. The highest gust of the year, 38.8 m/s. (87 mi/hr.), occurred on October 19, the highest hourly speed 20.0 m/s. (44.7 mi/hr.), on January 11, the highest mean daily speed, 15.3 m/s. (34.2 mi/hr.), on October 19 and the lowest mean daily speed, 0.3 m/s. (0.7 mi/hr.), on February 8.

The distribution of wind directions throughout the year differed little from normal. Winds from between south and west predominated in January, February, March, June, August, September and October, while the decrease in the frequency of south-westerly winds and the persistence of north-easterlies in May was very marked. In July the winds were mainly westerly and in December northerly.

Grass Minimum Temperature. There were 115 occasions of ground frost (i.e. grass minimum temperature not greater than 272·1°A. or 30·4°F.), but none of these occurred between June 19 and July 30; the number for December (21) equalled the previous December record (1925). The lowest grass minimum temperature was 260·0°A. (8·6°F.) on both December 23 and 24. The mean grass minimum temperature for each of the months January, February, November and December is less than 273·0°A. (32·0°F.), the mean for December being the lowest for that month on record.

Cloud and Weather.- (A) the mean amount of cloud observed at the six hours of observation is 7.4, which is a little below the normal. June with 8.4 has the largest mean amount, and May with 5.6 has the smallest. The largest mean amount for an observational hour is 9.1 at 9h in June; the least is 4.6 at 18h in May. There were no days, on which no cloud was seen at the normal hours of observation. On 27 days the amount 10 was recorded at every hour of observation.

- (B) Thunder was heard on 11 days, while there were observations of solar halo on 15 days, and of lunar halo on 4 days, and of aurora or auroral glow on 10 days.
- (C) The numbers of occasions on which the range of visibility was estimated to be (1) less than 1000 metres (1100 yards), corresponding with the entries X to E, and (2) at least 20 kilometres ($12\frac{1}{2}$ miles), corresponding with the entries k, 1, m, are summarized below. The limitations to which the estimates of visibility are subject are mentioned on p. 154. It is to be noted that the group (1) above consists of the occasions which are held to merit the description "fog, moderate, thick, or dense", while the entries k, 1, m, denote "very good or excellent visibility".

There were fewer occasions both of fog and of estimates K,l, and m than in 1934. Fog was most frequent in February and June, but entirely absent (at the standard hours of observation) in July. There were 83 estimates of m, visibility 50 km. (31 mi) or more, distributed among 46 days, 51 of the occasions were associated with increasing barometric pressure, and 53 with winds from west-south-west through north to north-east.

ATMOSPHERIC ELECTRICITY

Notes on the Instruments

Autographic records of atmospheric electrical potential gradient were obtained by means of an electrograph of the Kelvin water-dropper type, the potential at the water-jet being registered by a Dolezalek quadrant electrometer. On January 4th 1933, the double nozzle of the water jet was altered to a single nozzle; otherwise in all essential details the electrograph arrangements, the method of making scale tests and the method of reducing the autographic curve readings to potential gradient in the open were as described in "The Observatories' Year Book," 1928, pp. 160-161. Insulation tests were carried out each day, using an eye-reading method. The system was charged, and the fall in potential during a two minutes interval was measured by noting the change in position of the spot of light on a scale placed in front of the recording drum.

The scale value of the photographic record obtained by means of the Dolezalek electrometer used in conjunction with the water-dropper remained at about 2.0 to 2.1 volts per mm. throughout the year. The number of determinations of the reduction factor (i.e., the ratio of the potential at one metre above the ground in the open to the potential at the water-jet) was about six per month, each determination being based on fifteen or more readings (at intervals of half a minute) of the potential in the open. The values of the monthly reduction factor finally adopted for 1935 were obtained by a smoothing process, the adopted value for a given month being $\frac{(a+2b+c)}{4}$ where a, b, c, are the unsmoothed monthly mean factors for the three successive months centred in the given month.

All determinations of scale value and reduction factor were obtained with a particular Wulf quartz-thread electrometer. This instrument was calibrated

by means of a high tension battery, the potentials of which were measured by a potentiometer and standard cell. According to the scale value adopted for the Wulf electrometer in 1935, the instrument had about the same sensitivity as in 1934.

IDENTIFICATION NUMBER OF INSTRUMENT USED IN 1935

Wulf bifilar electrometer 3040

Notes on the Tables and Results

As far as possible an electrical character figure is assigned to each day and values of potential gradient are assigned for 2-3h, 8-9h, 14-15h, and 20-21h G.M.T. of all days, while values for all hours are assigned on days classified as Oa, la, or 2a. The character figures are given in Table 268, the significance of these symbols being as follows:-

- O, denotes a day during which from midnight to midnight no negative potential was recorded.
- 1, denotes the existence of negative potential at one or more times during the same period, but with a total duration of less than three hours.
- 2, denotes negative potential extending in the aggregate over three hours or more during the same period.
- a, denotes that within the 24 periods of 60 minutes for which an estimate of the mean potential gradient has to be made in the process of tabulation there was in no case a range of potential gradient in the open exceeding 1,000 volts per metre.
- b, denotes that, during the same period, a range of 1,000 volts or more per metre was reached in one hour at least but in fewer than six hours.
- c, denotes that, during the same period, a range of 1,000 volts or more per metre was reached in at least six hours.

Table 265 contains the values of electrical potential gradient at 2-3h, 8-9h, 14-15h, and 20-2lh G.M.T.; the value for a given hour represents the mean for the period of 60 minutes between exact hours, instead of centering at the exact hour, as was done in years prior to 1932. Blanks indicate that the trace was in some way defective. If it is possible to assign an approximate value of the potential gradient on such days, this value is given in brackets. The reduction factors, used in converting the potential at the water-jet to potential gradient in volts per metre in the open, are also given.

In Table 266 are given, for Oa days, (1) the mean diurnal inequalities for the months, seasons and year, (2) particulars of the number of days and of the non-cyclic changes and (3) the corresponding mean values of potential gradient. The inequalities, or the mean values, for the year and seasons are the means of the inequalities or means respectively, for the appropriate months.

Corresponding data for la and 2a days combined appear in Table 267.

It should be noted, that in these tables, "Winter" denotes the four months January, February, November, December; "Equinox" the four months March, April September, October; and "Summer the four months May to August.

In addition to the electrical character for each day, Table 268 contains the daily, monthly and annual values of duration (in hours and tenths) of ne-On 22 days of defective record when negative gative potential gradient. potential may have occurred dashes are entered; the sign of the gradient has been assumed positive during periods of defective recordin which no precipitation was observed. If precipitation was recorded for less than an hour during such defective periods an approximate value of the duration of negative potential for that hour has been assigned, and the total for the day given in brackets. When, during highly oscillatory gradients, there was uncertainty as to the times of changes of sign, half of the total duration of doubtful sign was accounted negative. The total duration of negative potential gradient in each month and the average daily duration are entered in the lower part of For the 363 days of assignable duration of negative potential the table. gradient the total number of hours was 790.8 as compared with 838.1 in 1934; an average of 2.18 hours per day, as against 2.37 hours per day in 1934.

Following the practice adopted in 1923, the mean values of potential gradient given in Table 265 are of two kinds, viz., (a) the mean of all the positive values of potential in the column and (b) the algebraic mean derived from all days on which all four hours were represented. The mean values for the month, as derived from the (a) and (b) values respectively, are shown in the last line, and the means for the year are given at the foot of the December table. It is to be expected that the mean derived from the values at 2-3h, 8-9h, 14-15h, 20-2lh, on a sufficiently large number of days, will approximate closely to the mean value derived from all hourly values of all the days.

The (a) mean exceeds or is equal to the (b) mean in every month excepting February, March, May, June and September and is exceeded by the mean value on Oa days, in all months excepting November. The general tendency is for 1935 values to be higher than those of 1934, this being the case in five months for both the (a) mean and the (b) mean.

Annual mean values for recent years, derived by giving equal weight to the twelve monthly means, of the (a) and the (b) means and of the means for Oa days are as follows:-

as I	OTTOME	3: -			0av	(a) v/m.	(b) v/m.

1934	• •	• •	• •	• •	233	201	190
1935	• •	• •	• •	• •	231	203	200

The highest values of both the (a) and (b) means occur in December. The mean value of Oa days is highest in February, being 342 volts per metre.

Noteworthy occasions of high potential gradient were as follows:-

- (1) January 12d 2h 37m to 8h 8m and January 12d 18h 13m to 2lh 26m. During the earlier period snow fell and was accompanied by lightning whilst in the latter the sky was cloudless and the ground snow covered. On both occasions the potential gradient remained continuously above 600 v/m and at times exceeded the upper limit of registration (+1140 v/m).
- (2) January 13d 12h 4m to 16h 7m. During this period intermittent snow fell, the upper limit (1150 v/m) of potential gradient was at times exceeded while the potential gradient, excepting for a momentary drop, remained above 600 v/m.
- (3) January 15d 15h 47m to 20h 11m. During this period of fog the potential gradient remained above 570 v/m and for more than an hour continuously exceeded the limits of registration (1140 v/m).
- (4) January 29d 15h to 30d 0h 6m. During this period of clear skies, the potential gradient remained above 550 v/m and at times exceeded the limit of registration (1170 v/m).
- (5) February 9d 18h 24m to 22h 17m. Potential gradient was above 580 v/m throughout and for a brief period exceeded the limit of registration (1170 v/m).
- (6) June 24d 22h 45m to 25d 6h 13m. Associated with a low stratus cloud sheet the potential gradient remained over 580 v/m throughout, the extreme being 1000 v/m and the average about 740 v/m.
- (7) November 24d 19h 57m to 25d 3h 28m. Fog developed during this interval and, apart from two brief intervals, the potential gradient exceeded 500 v/m, the maximum being 1280 v/m and the average approximately 800 v/m.

The following were the noteworthy occasions of continuous negative potential gradient:-

- (1) March 29d 12h 45m to 19h 8m. Continuous slight rain fell during this period. The lower limit of registration (-850 v/m) was exceeded for an aggregate time of more than three hours.
- (2) April 16d 1h 17m to 9h 32m. During continuous rain. potential gradient remained negative, the lower limit of registration (-860 v/m), apart for a brief period, being continuously exceeded throughout.
- (3) September 18d 2lh 12m to 19d 4h 29m. During this period of continuous rain, heavy at times, the lower limit of registration (-930 v/m) was exceeded frequently.
- (4) October 8d Oh 2lm to 6h 24m. Rain, heavy at times, fell throughout the period during most of which the potential gradient exceeded the lower limit of registration (-910 v/m).

(5) November 20d 23h 23m to 21d 7h 42m. Continuous light rain fell during this period in which the lower limit of registration (-810 v/m) was exceeded for an aggregate of nearly 4 hours.

On the following occasions long period of negative potential gradient were broken by short excursions to the positive side:-

- (1) February 16d 3h 16m to 15h 10m. Rain fell continuously during this period and, apart from four very brief excursions to the positive side, the greatest reaching +34 v/m, potential gradient was negative throughout, the lower limit of registration (-810 v/m) being frequently exceeded.
- (2) February 20d 2h 48m to 13h 12m. Apart from one brief excursion to +38 v/m, potential gradient was negative throughout and for the greater part exceeded the lower limit of registration (-810 v/m). Rain, heavy at first, fell continuously.
- (3) April 16d 15h 45m to 17d 9h 18m. The potential gradient, apart from two excursions to the positive side of 14 minutes and 6 minutes respectively during the latter of which it reached +90 v/m, was negative and for an aggregate of over 12 hours exceeded the lower limit of registration (-840 v/m). Rain fell nearly continuously.
- (4) May 15d 10h 10m to 17h 53m. During this period of snow, sleet and rain, apart from a very brief excursion to +66 v/m, potential gradient was negative and continuously below the limit of registration (-850 v/m).
- (5) August 30d llh 13m to 22h 43m. During this period of negative potential gradient there were several short excursions to the positive side, the value of the potential gradient in 5 of these exceeding the upper limit of registration (1000 v/m). There was continuous rain, heavy at first, throughout the period and the potential gradient frequently exceeded the lower limit of registration (-970 v/m).
- (6) October 5d 2h 4m to 14h 27m. During one excursion of three minutes duration to the positive the potential gradient reached +6l v/m, but otherwise remained negative throughout, the lower limit of registration (-910 v/m) being exceeded for an aggregate of more than 5 hours. Rain fell continuously.
- (7) November 15d 4h 42m to 1lh 4m. There was one brief excursion to +158 v/m near the end of this period. Apart from this the potential gradient remained negative and exceeded the lower limit of registration -850 v/m during an aggregate of over 4 hours. Rain fell continuously.

There are considerable irregularities in the mean diurnal inequalities of potential gradient on Oa day's for individual months, although in all months, excepting April, the principal maximum occurs in the late evening. When compared with normal values for 1911-21 the mean diurnal inequalities for the seasons, summer and equinox, correspond fairly closely to normal, excepting that the principal maximum is more prominent. In the mean diurnal inequality for

tne winter season, the chief difference is that the principal minimum is intensified.

TERRESTRIAL MAGNETISM

Notes on the Instruments

The standard magnetographs¹, which have been in regular use since 1909, are situated in the east chamber of the underground magnet house and until December 31, 1931 they were arranged so as to record changes of the three geographical components of terrestrial magnetic force, viz., the north component, N (or + X), west component, W(or - Y), and the vertically downward component V (or + Z). From January 1, 1932, the instruments recording changes in the north component, N, and the west component, W, were altered so as to record changes in the horizontal component, H, and the magnetic declination, D, respectively.

The instruments for the north and west components were of the Adie bifilar type, in which torsion of the bifilar suspension, of fine tungsten or steel wire, is utilised to bring the magnets into an azimuth approximately perpendicular to the directions of the components whose changes they respectively record. The alteration to the north component instrument consisted in turning the torsion head of the suspension until the magnet was in the azimuth perpendicular to the magnetic meridian. The alteration to the west component instrument consisted in replacing the bifilar tungsten wire suspension with a unifilar suspension of eight strands of unspun silk. In each of these instruments the magnet is about 13.8 cm. in length and is suspended within a copper shell, or frame, of suitable dimensions to ensure that the movements of the magnet are sufficiently damped. To the magnet is rigidly attached a semi-circular plane mirror, immediately beneath which is a fixed mirror of similar form and dimensions. Each magnet and mirror system is contained within a brass cylindrical case, cemented on to a pier and surmounted by a tall bell-jar of glass. Light from a brightly illuminated slit passes through a collimator, is incident upon the two mirrors and after reflection passes along a wooden channel and thence, through a horizontal hemi-cylindrical lens, to a photographic paper wound on a clock-driven cylinder. The hemi-cylindrical lens is set in the side of the case containing the recording drums, and matters are so arranged that the beams of light reflected from the two mirrors are brought to a focus by the lens which condenses the two vertical images to two sharply focussed dots on the paper. Hence the record obtained consists of two traces, the one straight and known as the base line, the other curved and representing the angular movements of the suspended magnet, and therefore the changes in the component of terrestrial magnetic force.

The standard instrument for the vertical component is a Watson multiple-magnet balance.² In this instrument the magnet system consists of eight magnetised steel rods, each 10 cm. long and 0.2 cm. in diameter, carried by an aluminium frame to the centre of which are attached the moving mirror and also the knife-edge, which bears upon an agate plane and about which the system balances. Copper damping plates and a temperature-compensating device are provided. The recording arrangements are similar to those describ-

¹ For a general description of magnetograph arrangements see "A Dictionary of Applied Physics," Vol. II, Macmillan, London

²Terrestrial Magnetism, Vol. VI.

ed above, save that the hemi-cylindrical condensing lens and the recording drum are vertical.

One clock serves to operate the three drums and also makes the time marks at two-hourly intervals.

To the containing case of each instrument is fitted a drying tube containing calcium chloride.

A determination of the azimuth of the magnet of the horizontal component magnetograph is carried out each year by comparing the deflections produced by an auxiliary magnet with its axis (a) magnetic east-west and (b) inclined at a known small angle to this azimuth. Drift of the magnet system of the Watson balance has been compensated from time to time in the past by adjusting the position of a small control magnet which was fixed vertically to the lower part of the pier on which the balance stands. This control magnet was removed during October 1932 and has not since been replaced.

The azimuth lines in use in the east chamber are those which were determined in 1914 and of which particulars are given on p. 70 of "Hourly Values from Autographic Records, Geophysical Section", 1913.

The diurnal range of temperature in the east chamber of the magnet house is normally negligible. Temperature is ascertained daily at 10h by the thermometers within the instrument cases. The daily values appear in Tables 272, 276, etc.; the monthly means of the readings so obtained during 1935, together with the mean values for the years 1911-1933, were as follows:-

May June July Month. Feb. Mar. Sept. Oct. Nov. Dec. Jan. Apr. Aug Mean 1935 4.0 3.3 2.9 2.7 3.1 3.9 5.3 6.4 6.8 6.3 6.3 4.2

EXCESS OF MEAN TEMPERATURE ABOVE 280°A.

The annual range of temperature during 1935 was 4.4°C., the mean range for the previous twenty-four years being 4.3°C.

The temperature coefficient of the Horizontal Force variometer (formerly the N component variometer) has remained sensibly constant for many years.

In issues of the Observatories' Year Book for years earlier than 1933 the temperature coefficient of the Vertical Force magnetograph has been given as +26 γ per 1°C. A recent re-examination of the question shows that this was approximately the value until early in 1929. During that year however several adjustments were made to the instrument and as a result of these the temperature coefficient apparently was considerably reduced. The trend of base line values in relation to temperature variations in the magnetic chamber shows that in 1930 and 1931 the temperature coefficient of the vertical force variometer was about +10 γ and that in 1932 and 1933 and part of 1934 the coefficient was approximately +13 γ per 1°C. By the latter part of 1934 the coefficient had reverted to +26 γ per 1°C. and it has remained between +20 γ and +25 γ per 1°C. throughout 1935.

Determinations of scale value of the standard magnetographs are carried out at intervals of two weeks. The method adopted is that due to Broun. It consists essentially in measuring the photographically recorded deflection of the suspended or pivoted magnet produced by an auxiliary or test magnet situated at a known distance from the deflected magnet. Two sets of relative positions of the deflecting and deflected magnets are used. H and D instruments they may be termed the "end on" and "broadside on" positions, the magnet axes being in one plane. In the case of the V instrument the deflecting magnet is vertical; in one position the line joining its centre to that of the deflected magnet is collinear with the axis of the latter, but in the other position it is perpendicular thereto. occasion deflections are produced with the test magnet first on one side of the deflected magnet and then, at the same distance, on the other side, two deflections being produced at each side by reversal of the test magnet. Thus four deflection dots are obtained on the record. The two sets of relative positions of the magnets are employed on alternate occasions. The distance between the deflected and deflecting magnets is 90 cm., and approximate values of the double deflections produced are 47 and 93 mm. for the H instrument, 45 and 89 mm. for the D, and 58 mm. for the V. In deducing the scale values the force producing the deflections on the H and V instruments is determined from the deflection on the D instrument of which the scale value is known from its dimensions. The advantage of the method lies in the fact that by using the same deflecting distance in all cases, the magnetic moment of the test magnet is eliminated.

In the following table are given the scale values, obtained by overlapping means, which were employed in reducing the curve readings for 1935.

SCALE VALUES OF THE MAGNETOGRAPHS (y per mm. on the paper).

·	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept	Oct	Nov	Dec.

Vertical Force	3-77	3•76	3•75	3•74	3.74	3•76	3•79	3•79	3•79	3•79	3•79	3•79
Declination					1 mm	. = 1	600 o:	r 4.8	2γ			

In addition to the standard magnetographs there are in the west chamber of the underground magnet house auxiliary instruments of the Adie pattern (formerly the standard instruments at Kew Observatory) which also record changes in declination, D, horizontal force, H and vertically downward force, Declination records have been obtained since August, 1927, while the vertical force (Adie) and horizontal force records commenced in March and December, 1928. The general arrangements of these instruments are similar to those of the instruments in the east chamber. The declination magnet is suspended by a bundle of silk fibres (the torsion effect of which is negligible) and the scale value of the record is 1:17 to 1 mm. The vertical force balance consists of a single magnet, of which the dimensions are approximately 13.5 cm. x 2 cm. x 0.2 cm. With the object of reducing loss of record during magnetic storms the scale values of the auxiliary H and V records are arranged to be considerably greater than those of the standard H Thus, in 1935 the scale values of the Adie H and V records were approximately 10y and 5y per mm. respectively. Determinations of scale value are made by the method due to Broun. To facilitate the necessary adjustment, from time to time, of the azimuth of the horizontal force magnet, magnetic meridian lines (and lines perpendicular thereto) representing a sufficient range of values of declination were laid down in the west chamber in December, 1928, on the basis of simultaneous observations of declination in the chamber and in the east magnetic hut.

An auxiliary la Cour magnetograph of the quick run type, recording H, D, and V, was installed in the west chamber of the underground magnet house in connection with the second International Polar Year and has been continued since then.

The routine absolute observations of the magnetic elements are made in the east magnetic hut; as a rule two complete sets of observations are made every week, but generally determinations of declination and horizontal force are made on nearly every week-day. Declination is determined by means of the Kew pattern unifilar magnetometer (which was employed by Rucker and Thorpe in their magnetic surveys of the British Isles, 1886-1892) placed on Pier No.5. Determinations of horizontal force have in general been made daily with a Schuster-Smith Coil magnetometer placed on a pillar erected specially for it and approximately once weekly throughout the year with the Kew pattern unifilar magnetometer mentioned above. Determinations of inclination (dip) are made by means of the Schulze inductor on Pier No. 6.

For a detailed description of the method of observation with the Kew pattern magnetometer reference should be made elsewhere.

In determining declination four readings are taken, two with the magnet erect, two with the magnet inverted. A correction is applied to the mean of the observations for the observed torsion in the silk suspending fibre. The fixed mark is about one half-mile (0.8 km.) distant from Pier No. 5, and its bearing is taken as 8° 12′ 30″ west of south

Determination of horizontal intensity with the Kew unifilar magnetometer comprises observations of (a) the time of vibration of the collimator magnet, and (b) the deflection of a mirror magnet by the collimator magnet. Formerly deflection observations were made for three distances of the collimator

¹Dict. of Applied Physics, Vol. II, p. 532 or Stewart and Gee's "Practical Physics."

magnet, the order of the positions of the latter being: on east arm at 35cm. 30 cm., 25 cm.; on west arm at 25 cm., 30 cm., 35 cm. Thus the mean times for the deflections at the three distances were very nearly, if not exactly, identical and the observations were concentrated at the 25 cm. distance. Commencing on April 28, 1931, deflections were observed at 25 cm. only, except on one occasion per month when deflections were observed at the three disstances 35 cm., 30 cm. and 25 cm. By observing deflections at 25 cm. only the time of observation is reduced by about 16 minutes. The time interval between the mean times of the vibration and deflection experiments is usually about half an hour. The horizontal intensity, H, is calculated from H = $\sqrt{mH_{rr}} \times H_{rr}/m$ where mH_{rr} is obtained from the vibration experiment and H_{rr}/m from the deflections made at the 25 cm. distance, m being the moment of the colli- H_r/m is corrected for the distribution of magnetism in the mator magnet. From the latter part of 1913 until the end of 1923 the value of magnets. this correction, viz., $\log_{10}(1 + P/25^2 + Q/25^4)$, applied to the observations of a given month was a mean value derived from the observations obtained during the seven months including the given month as fourth of the seven. values so derived show considerable fluctuations, and it is improbable that P and Q actually varied to the extent implied. Commencing in 1924 the value of the correction used in reducing the horizontal intensity observations has been the mean of the mean values for each of the years 1917-24, 1917-25, etc. The mean value of the logarithm for the years 1917-35 is $\cdot 00543$. A variation of $\cdot 00020$ in the value of \log_{10} (1 + P/25² + Q/25⁴) corresponds with a variation of about 4y in the derived value of H.

The values of P, Q, and $\log_{10} (1 + P/25^2 + Q/25^4)$ for individual years are as follows:-

Year		P	Q	log ₁₀ ($1 + P/25^2 + Q/25^4$

Though observations of horizontal force have continued to be made once weekly with the Kew Magnetometer, the absolute standard as from 1st January 1934 has been the Schuster-Smith Coil. This instrument was installed at the observatory in February 1931 and a first series of comparative observations extended from October 1931 until June 1933 when the potentiometer was returned to the makers in order that certain alterations might be incorporated in it.

After recalibration at the National Physical Laboratory the potentiometer was returned to the Observatory and the Coil was brought into daily use.

A complete description of the Schuster-Smith Coil and of the method of observing with it is given in the Philosophical Transactions of the Royal Society, A.Vol.223 (1922), pp. 175-200. Essentially the instrument consists of a Helmholz-Gaugain system of two coils of wire accurately wound on a hollow marble cylinder. A small magnet is suspended at the centre of the coil system. The current passing through the coils is very accurately adjusted by use of a Broca Galvanometer in a potentiometer circuit in which the electromotive force across a known resistance is balanced against a Weston Standard cell. The principle of the instrument is that a horizontal magnetic field, slightly greater than the earth's field and almost opposite to it in direction, is set up through the coil system. By suitable adjustment of the current through the coils this coil field can be arranged to be of such a magnitude that the resultant field, as indicated by the alignment of the magnet at the centre, is exactly at right angles to the earth's field. In this equilibrium position if a is the angle between the direction of the earth's field and that set up by the coils, if F is the constant of the coil system (i.e. the field due to unit current through the coil) and i is the current, then

$H = Fi \cos \alpha$

The replacement of the Elliott No.60 Kew Type magnetometer by the Schuster-Smith coil as standard has involved a discontinuity of -14 γ in H and correspondingly -38 γ in V as from 1st January 1934. This fall in H has been established by a long series of intercomparisons between the old and new standards. Of the total amount of 14 γ it has been estimated that 10 γ is accounted for by departure of the moment of inertia of the magnet system of the Elliott magnetometer from the value as originally determined and as used up to and including the year 1933 in the reduction of the results of absolute observations. When the most recent determinations of the moment of inertia are incorporated the values of H determined by the Elliott magnetometer are lowered by 10 γ . If this change came in gradually throughout a period of about twenty-five years it will have affected the calculated secular changes to the extent of less than $\frac{1}{2}\gamma$ per annum.

The remaining 4 γ of fall between the Elliott determinations, corrected as described above, and the determinations made by the Schuster-Smith Coil is to be regarded as the net change arising from instrumental differences.

On the basis of a short series of observations made at Eskdalemuir in January 1933 by an officer from the Royal Observatory, Greenwich, using Kew Magnetometer Casella No. 181 as a travelling standard, it was deduced that the Eskdalemuir Schuster-Smith Coil reads about 5γ lower than the Abinger Coil; this means that the Elliott No. 60 determinations, corrected for the revised moment of inertia of magnet, apparently read only ly different from the Abinger Coil. These results are, however, subject to some uncertainty and it was decided that the Eskdalemuir Coil, without any correction, should be used from 1st January 1934 as the absolute standard for Eskdalemuir. Thus, as already indicated, changes of -14γ in H and -38γ in V must be kept in mind in comparing the published results for 1933 and earlier years with the results for 1934 and later years.

The Schulze inductor consists essentially of a coil of insulated wire which can be rotated continuously and rapidly about an axis which coincides with a diameter of the coil. This axis is capable of rotation about a horizontal and vertical axis. The inclination and azimuth of the coil axis are read off on a vertical and horizontal scale respectively. The windings of the coil are led off from a commutator to a Broca galvanometer. To effect a determination of magnetic inclination, the coil is then rotated steadily at the rate of about 360 revolutions per minute and the inclination of the axis of rotation is adjusted until the galvanometer deflection is the same in magnitude and sign whether the sense of rotation is positive or negative. this position the rotation axis of the coil coincides with the direction of the earth's field and the inclination to the horizontal may be read off from the vertical circle. Two series of settings are made, one with the vertical circle facing east, the other with the circle facing west.

The base line values of the magnetograph records are deduced from the results of the absolute observations, any of the latter obtained during times of considerable disturbances being excluded.

In the case of horizontal force and declination, the equivalent value of the mean curve ordinate, corresponding to the period of observation, is subtracted from the observed value of the element to give the deduced base line value of the record. Similarly, by the combined use of the curve ordinates at the times of the inclination and horizontal force observations the value of H corresponding to the inclination observations is obtained and thence the base value for V. The base line values finally adopted are obtained from a curve drawn smoothly through points given by the deduced values, due allowance being made for discontinuities in the records.

Some of the absolute determinations of D, I and H are summarized in the subjoined table. Considerations of space make it necessary to limit the observations printed to about two per week, but, as indicated above, absolute observations of some of the elements are made more frequently. For each set of absolute observations are shown the deduced base line values, of H, D, and V and, in brackets, the adopted base line values. Thus, an entry 16210 (11) signifies: - deduced base line value 16210, adopted base line value16211. The adopted values were obtained as described in the foregoing, and therefore the base line values corresponding to dates between those given in the table may be obtained by interpolation.

The hourly readings are obtained from the magnetograms, standardized as described in the foregoing, by means of a ruled glass scale. The reading for any given hour G.M.T. is that ordinate estimated to be the mean reading for 60 minutes between exact hours. The product of this ordinate and the scale value is added to the adopted base line value, and the sum so obtained is the hourly value printed in the tables.

IDENTIFICATION NUMBERS OF INSTRUMENTS IN USE IN 1935

Unifilar Magnetometer, Kew pattern .. Elliott, No. 60. (with collimator magnets 60a and "no number", and mirror magnet, 60c).

Schuster-Smith Coil Magnetometer, Cambridge Inst.Co. No.37629. (with Standard Cell No. L34635 and Potentiometer No. L35968)

Dip Inductor Schulze, No. 103.

Notes on Tables

The hourly values of H, D and V, obtained as described above, appear in three of the four monthly tables. The mean value for the day is computed as the mean of the twenty-four hourly values.

The letters "Q" and "D" denote the five quiet and the five most disturbed days as selected at De Bilt.

In the fourth table for each month are given:-

- (a) the values and times of the daily maximum and minimum and the values of the absolute daily range for each of the elements H, D and V.
- (b) the value of HR_H + VR_V for each day, where R_H, R_V denote the absolute ranges for a calendar day of the horizontal and vertical components. (This measure of magnetic activity was adopted in 1932 by the International Commission for Terrestrial Magnetism and Atmospheric Electricity. In volumes of The Observatories' Year Book prior to that of 1932 the values of the quantity R_N²+R_W²+ R_V² were used as a measure of activity).
- (c) the daily magnetic character figures, assigned according to the international scheme, wherein "0", "1", "2", respectively, denote quiet, moderately disturbed, and highly disturbed conditions.
- (d) the daily values of temperature in the underground magnetograph chamber.

Mean diurnal inequalities of the components N, W, V, H, D, and I on all days and on international quiet and disturbed days are given, for the months, seasons and year, in Tables 317 to 334. In calculating diurnal inequalities the non-cyclic change has been eliminated on the assumption that its timerate is linear. The inequalities of N,W, and I have been computed from those of H, D, and V, by means of the formulae:

$$\delta N = \cos D. \quad \delta H - \frac{\pi}{180 \times 60} \quad H \sin D.\delta D$$

$$\delta W = \sin D. \quad \delta H + \frac{\pi}{180 \times 60} \quad H \cos D.\delta D$$

$$\delta I = \frac{180 \times 60}{\pi} \cos I \quad \left(\frac{\delta V \cos I - \delta H \sin I}{H} \right)$$

in which D and I are expressed in minutes of arc, and where H, D, and I for any given month are the respective mean values for that month as published in Table 338. The values of the range of the mean diurnal inequalities of the several elements on the three different types of day are brought together in Table 335, and the values of the non-cyclic change of H, D, and V are given in Table 336.

The results of harmonic analysis of the mean diurnal inequalities of N, W, and V for the months, seasons and year are to be found in Tables 339 and 340, in which are given the values of a_n , b_n , c_n , and a_n , in the two equivalent series $\sum (a_n \cos 15nt^\circ + b_n \sin 15nt^\circ)$ and $\sum c_n \sin (15nt^\circ + a_n)$. In the former series t is reckoned in hours from midnight G.M.T., whilst the published values of a_n refer to Local Mean Time. The values of the harmonic coefficients have been computed from the inequalities as given in the tables and have been corrected, where necessary, on account of the fact that the hourly values are not instantaneous but mean values. The factors by which the coefficients have to be multiplied (vide Report of the British Association, 1883, p. 98) are 1.00286 for a_1 , b_1 , c_1 ; 1.01152 for a_2 , b_2 , c_2 ; 1.02617 for a_3 , a_3 , a_4 and 1.04720 for a_4 , a_4 . The values were obtained to two decimal places and finally were rounded off to 0.1 γ .

The mean values of $HR_H + VR_V$ are summarized in Table 337.

In years prior to 1934 Table 338 supplied for the separate months and year the mean values of N, W, V, T, D, I and H derived from all days. Similar data are still given but the table has been rearranged and extended to provide in addition the mean values of the primary elements H, D, and V on the internationally selected groups of quiet and disturbed days.

Tables 341 and 342 contain mean values of the magnetic elements for 1935 and recent years at a number of observatories.

Review of Results of Magnetic Observations

Mean and Extreme Values of the Magnetic Elements, 1935. The mean valuest are given below in Table 1 along with the corresponding values for the previous year. The values of H, D, and V have been computed from the hourly values derived from the autographic records of all days, standardized by

The seasons are defined for this purpose as follows:- "Winter", January, February, November, December; "Equinox", March, April, September, October; "Summer", May, June, July, August. †See remarks on p. 178.

means of the absolute observations; those of N, W, I, and T have been deduced from the values of H, D, and V.

1934 1935	16536 16525	14 13	0•6 48• 8	69 69	45·9 47·0	16044 16047	4003 3945	44859 44875	47810 47822

Westerly declination was on the average 11/8 less in 1935 than in 1934. The rate of decrease is practically the average rate of recent years. Between 1913 and 1920 the average rate of decrease was 9.35 The fall of 117 in H between 1934 and 1935 is to be compared with 87 between 1933 and 1934 (between which years the discontinuity of 147 was introduced; see 0.4.8. for 1932) and with 107 for the average annual rate of decrease over the 10 years 1923-32. The slight increase of 67 in N and the decrease of 587 in W are similar to the changes in these derived components in former years. Inclination increased by 1/1 between 1934 and 1935 compared with 0.7 for 1933 and 1934. After allowing for the discontinuity of 387 on January 1 1934, the change in V between 1933 and 1934 was a rise of 77; between 1934 and 1935 the rise was 167. With corresponding allowances the increases in T from the earlier to the later of these pairs of years have been 37 and 127.

Annual mean values derived from (a) international quiet days and (b) international disturbed days are as follows:-

(a) H, 16529γ ; D, 13° 48'9; N, 16051γ ; W, 3947γ ; V, 44874γ (b) H, 16520γ ; D, 13° 48'6; N, 16042γ ; W, 3943γ ; V, 44876γ

In comparing these with the values for the years before 1934 the discontinuities introduced on January 1, 1934 in H and V and the components derived from them must be kept in mind.

The differences between the mean annual values of N, W, and V, derived from all, international quiet, and international disturbed days in the years 1926-35 inclusive, are given below, together with the mean differences for the years 1915-25. In every year of the series quoted the mean value of N and of W on quiet days exceeded the mean value on all and on disturbed days. The only years in the period 1915-25, for which either the all or the disturbed day mean value of V exceeded the quiet day value were 1917, 1919, 1921.

Quiet day mear	ı-All day	mean	Quiet day m	ean-Disturb	ed day mean

The resultant vector representing the average excess of the mean values on quiet days over the mean values on all days, for the years 1915-1925, has a magnitude of 3 γ ; its azimuth is 336°, measured from true north through east, and it is inclined at about 77° to the downwardly directed vertical. The vertical plane which contains this vector approximates very closely in azimuth to the vertical plane passing through Eskdalemuir and the pole (taken as 78° N 68° W) of the axis of magnetization of the earth. (cf. S. Chapman, "On certain average characteristics of world-wide magnetic disturbance".Lond. Proc. Roy. Soc. Series A. Vol. 115, p.242.)

The extreme values of H, D, and V actually recorded during 1935 are given in Table II.

		Maximum			
Component	Value	Date, 1935	Value	Date, 1935	Absolute Annual Range
Horizontal Force	16675γ	d h m Sept.11 20 58	16362γ	d h m Apr. 11 10 38	313γ
Declination	140 11:7	Mar. 14 13 38 June 18 19 42	13° 14 ' 4	Oct. 21 18 12	57:3
Vertical Force	45019γ	Oct. 24 15 4	4473 1γ	Sept.12 3 6	288y

TABLE II

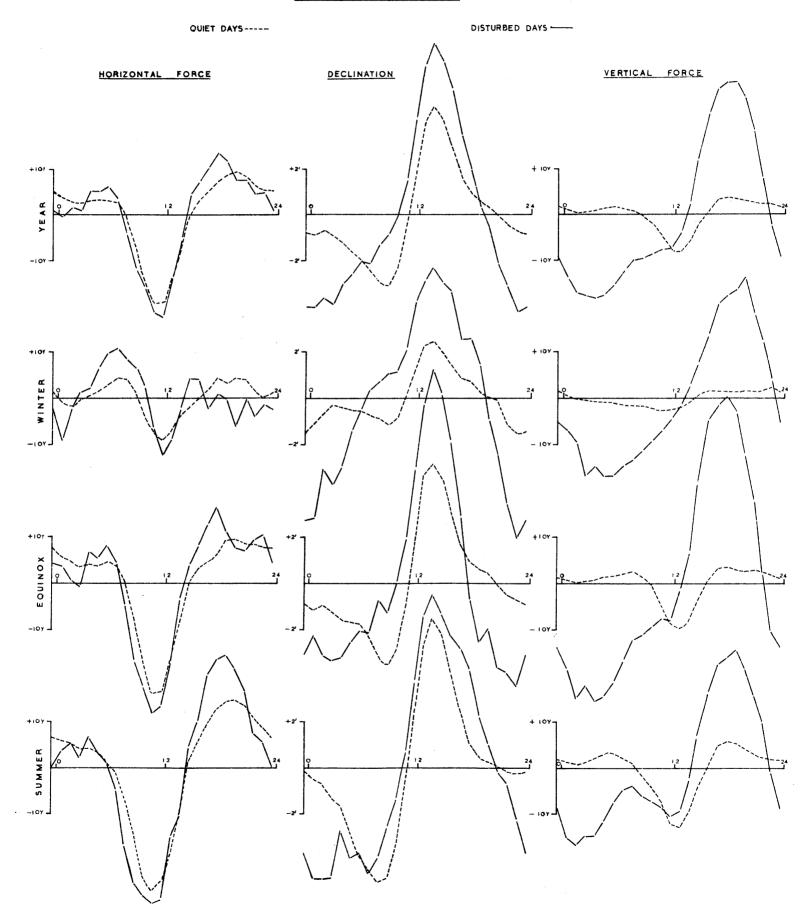

The range of 57.3 in declination is equivalent to a range of 275γ in the component of force perpendicular to the magnetic meridian.

Magnetic Character of the Year .- The Eskdalemuir practice of tabulating for each day the value of Σ R² has been discontinued in favour of the expression HR_H + VR_V presently being tried on an international basis as animerical measure for characterising days. The magnetic character figures on the scale 0, 1, 2 which were assigned in accordance with the international scheme are summarized in Table III. This table contains also the monthly mean values of the international character figures, which for 1935 are based on the estimates made at about 50 observatories, and the mean monthly values of HR_H + VR_V for all, international quiet (Q), and international disturbed (D) days.

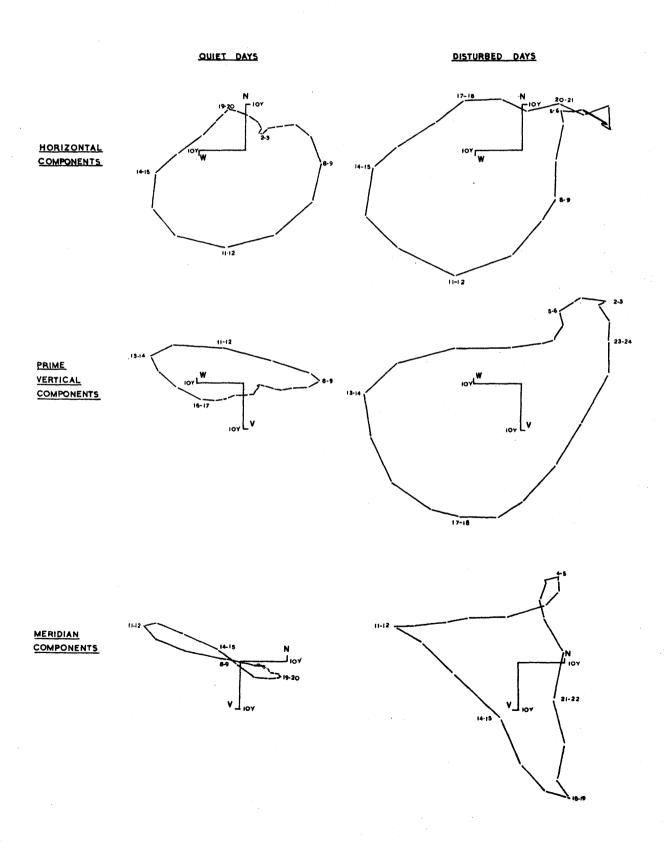

The Eskdalemuir mean value of HR_H + VR_V for the year, like the mean character figure, is greater than for 1934. The mean sunspot numbers for the years 1923-35, are, in order, 5.8, 16.7, 44.3, 63.9, 69.0, 77.8, 65.0, 35.7, 21.2, 11.1, 5.7, 8.7 and 36.1.

The mean values of HR_{H} + VR_{V} for all days suggest that September was the most disturbed month.

DIURNAL VARIATION OF THE MAGNETIC ELEMENTS ESKDALEMUIR 1935

VECTOR DIAGRAMS ILLUSTRATING DIURNAL VARIATION OF MAGNETIC FORCE ESKDALEMUIR 1935

In Table III the annual mean values are the means of the monthly values entered in the corresponding columns.

<u>Diurnal Inequalities</u>.- The mean diurnal inequalities for all days, and international quiet and disturbed days, for the months, seasons and the year, are given in Tables 317-334, and the corresponding inequality ranges in Table 335.

The inequalities of H, D and V for international quiet and disturbed days are shown graphically in Plate III, while in Plate IV are given vector diagrams illustrating the diurnal variation of magnetic force in the horizontal, the prime vertical and the meridian planes.

In 1935 the ranges of the annual mean inequalities of all components were greater than in 1934 for all three classes of days; the percentage increase is greatest for V on disturbed days and particularly so in the equinoctial months.

 $[*]NR_N + WR_W + VR_V$ in 1930 and 1931

^{10,000/2}

The average values of the diurnal inequality ranges for the year and seasons for the period 1916-26 (not the values of the range of the representative mean diurnal inequalities for this period) are given below, along with the 1935 values expressed as a percentage of the average values. The units employed are 1γ for force and 1' for declination. The mean sun spot number for 1916-26 is $46\cdot7$; that for 1935 is $36\cdot1$.

The 1	935	ranges are	nearly	all	below	the	average.

Daily Range. The values of mean absolute daily range for the months and seasons of the year, together with the corresponding means for 1916-26 are given in Table IV; the ranges are also expressed as percentages of the mean absolute daily range for the year. The declination ranges, measured in minutes of arc have been multiplied by 4.81 to convert them to units of force of the component perpendicular to the magnetic meridian.

The annual and seasonal mean daily ranges of H, D and V are all greater than the corresponding means for 1934.

The frequency distribution of absolute daily ranges recorded in 1935 is shown in Table V, which also contains the percentage distribution for the periods 1916-1926.

TABLE VI. PRINCIPAL MAGNETIC DISTURBANCES RECORDED AT ESKDALEMUIR 1935

Where the beginning of a disturbance has been marked by a "sudden commencement," the serial number is followed by an asterisk (*), and the time entered in the second column is that of the sudden commencement, estimated to the nearest minute. In other cases, the exact hour nearest the time at which disturbance may be regarded as having begun is entered in the second column. To the tabulated values of maximum and minimum the following have to be added:- H, 16000y; D, 13°; V, 44000y.

The intervals of maximum frequency in 1935 lie between 50 and 59γ for H, $60-69\gamma$ for D, and $20-29\gamma$ for V. For D and V these intervals are both 10γ higher than in 1934: for H 10γ lower.

On 22 days in 1935 the absolute range in either H or D was 160 γ or more. The numbers of such days for N and W in the years 1915 to 1931 and for H and D from 1932 to 1935 are shown in the accompanying table.

Year 1900+	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	3 0	31	32	33	34	35

The number of days in each year from 1926 on which the range in each of H, D and V was 2007 or more has been as follows:-

Year 1900+	26	27	28	29	3 0	31	32	33	34	35
No. of days.	18	7	5	9	16	1	2	1	2	0

Irregular changes in Declination.- In connexion with the supply of declination data to mine surveyors it has been the practice to classify the hourly periods between the exact hours G.M.T. into four groups according to the range in declination within each period. The range limits, which were adopted in consultation with representative mine surveyors, are:- less than 5', between 5' and 15', between 15' and 30', and greater than 30'. This method of classification has been applied to the declination records obtained in the year 1935, and the actual frequencies of occurrence of hourly ranges in the last three of the four divisions mentioned are set out below. A range of 30' is equivalent to a change of 144γ in the component of horizontal force perpendicular to the magnetic meridian.

Number of cases per month

												-	
Range Interval	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year.

On the average quiet day the most conspicuous change in declination is that from the most easterly value at about 8h or 9h to the most westerly value at about 13h or 14h, the rate of change being greatest between 10h and 12h. The hourly range due to the regular diurnal variation at this time of day is less than 5', but doubtless it happens at times that the occurrence of slight disturbance results in the hourly range exceeding 5', whereas the occurrence of the same degree of irregularity at another hour of the day would not cause the hourly range to exceed 5'. Thus the figures given above for the range interval 5'-15' tend to exaggerate somewhat the incidence of irregular changes between 9h and 13h. The hourly distributions of the frequency of occurrence of ranges between 5' and 15' and between 15' and 30' exhibit the well known tendency for irregular changes to occur predominantly during the "night" hours-at least in Europe.

Principal Magnetic Disturbances during 1935.— Particulars of the principal magnetic disturbances recorded during the year are given in Table VI. Corresponding information for the same disturbances is given in the Lerwick Section. The magnetograms for the most highly disturbed days are not reproduced in this volume, but photographic copies may be obtained on application to the Director, Meteorological Office, Air Ministry, Kingsway, London, W.C.2.

Remarks on Magnetic and Allied Phenomena, 1935

JANUARY .- (Average Character Figure 0.65)

Throughout most of the month and particularly between 6th and 14th and from 29d 2h to 30d 6h, conditions were mainly quiet. The first noteworthy disturbance continued from late on 16th to early on 19th, a fall of 72γ in V between 1h and 2h 14m on 17th being the outstanding feature, D oscillating through 25' during the same period. The 20th was comparatively quiet but minor disturbances occurred from 21st to 26th.

After another quiet day a movement of 'sudden commencement' type (-16 γ , +48 γ in H) at 27d 14h 50m was followed by some disturbance which persisted until 29d 2h. The chief feature was a rise in V through 70 γ between 18h and 20h on 27th.

FEBRUARY. - (Average Character Figure 0.79)

Slight disturbance occurred early on 1st followed by fairly large fluctuations (187 v in V, 118 v in H and 33.6 in D) during the night 1st-2nd. From 4th to 12th the disturbance was of a minor character, though a large sunspot in solar lat. -17° crossed the central meridian at 4.6 d*.

Activity increased early on 13th though ranges were not large until between 20h and midnight, H having peaks of 123γ and 148γ , D varying through 38° and V through 108γ during that period.

Disturbance diminished on 14th but continued intermittently and on a small scale for the remainder of the month; only 19th, 27th and 28th were quiet.

MARCH. - (Average Character Figure 0.74)

Conditions were fairly quiet till about 12d 23h when disturbance set in which continued intermittently till 17th. The greatest movements were 163 γ in H, 183 γ in V and 49·1' in D and occurred in the period 14d 9h to 15d 2h. At this time there was a sunspot, central meridian passage 15·2d*. Apart from some further disturbance during 20th to 22nd and on 24th, conditions were relatively quiet till 30th. A movement (-27 γ , +73 γ in H) of 'sudden commencement' type at 30d 12h 13m was followed by 10 hours of comparatively small disturbance in which the major fluctuation was a drop of 68 γ in H at 14h 40m.

APRIL. - (Average Character Figure 0.70)

After seven consecutively quiet days at the beginning of the month, slight disturbance occurred on 8th and 9th.

This was followed by another quiet

*"The Observatory" February 1936.

interval (9d 17h - 10d 8h) after which the only notable disturbance of the month began. Activity increased after noon on 10th. V attained maxima at 18h 34m and 20h 25m then fell 163y to its minimum at 11d 1h 55m. After a period of continuously irregular fluctuations, H fell to its lowest value of the year, 16362y, at 11d 10d 38m, then rose by 243y in a series of peaks to reach its maximum during the disturbance at 21h 9m. The range in D in the disturbance was 35·1'. There was a small spot on the sun's disc about this time, central meridian passage 9·4d.*

Except for a rise in H of 132 γ in 20 minutes just before 17h on 12th and a similar though multiple movement at about the same time on 13th the disturbance diminished throughout both these dates. From 14th to the end of the month conditions remained fairly quiet, the quietest periods being from 20d 2h to 23d 8h and from 23d 18h to 30d 7h.

MAY .- (Average Character Figure 0.65)

Disturbance began with a movement of 'sudden commencement' type at ld 12h 47m (-6\gamma, +45\gamma\) in H), after which H fluctuated rapidly through 169\gamma\), reaching a maximum just before 16h. Activity decreased temporarily but recommenced at about 23h, when H, D and V all fell sharply (D through 34'), though not simultaneously. V did not reach its minimum until after midnight. A slow irregular rise followed and conditions became quiet at 2d 5h. The ranges during this disturbance were 169\gamma\) in H, 48.0' in D and 128\gamma\) in V.

Conditions continued to be quiet, especially after 3d 22h, until late on 10th, when slight disturbance commenced which lasted until 12d 8h. The 14th and 15th were quiet. Slight activity on 18th and 19th was followed by more marked disturbance on 20th, the chief features being a peak in D of 22' at 3h 38m and falls of 90γ in V, 104γ in H. The minima in these elements were reached at 4h 4m and 7h 14m respectively. Slight activity continued for a further 48 hours and during the remainder of the month only minor disturbance was recorded.

JUNE, - (Average Character Figure 0.77)

The first 3 days were quiet and only minor movements occurred on the next Disturbance set in about 7d 12h. After a peak of 102y amplitude, Hoscillated rather rapidly while rising to a rounded maximum at 16h 15m. then fell more steadily to a minimum at 22h 3m. This was immediately followed by another large up-and-down movement in which the rise of 196 y took 26 min-A dip of 104y just after 2h on 8th was the only other noteworthy movement in H. Until 7d 2lh the trend of the disturbance in D closely followed that in H, though on a reduced scale. After 21h the direction of the D oscillations was reversed relative to those in H and increased in range. The decrease in D between 22h 4m and 22h 24m was 27', and the minimum attained shortly after midnight was 30' below the mean for that period. about 1h on 8th the movements in D were again more closely parallel with those V rose steadily to its maximum at 7d 19h 26m, fell more rapidly through 176y to a double minimum just after 22h and then, after a slight recovery, to another, less sharp, minimum, 12y lower at 8d 2h 38m.

Activity decreased after 8d 3h but continued intermittently till the evening of 1lth, especially during the daylight hours. About this time there

^{* &}quot;The Observatory" February 1936.

was a moderate sunspot, central meridian passage 10·2d*. H reached its maximum for the whole disturbance at 11d 16h 56m. Ranges for the period 7d-11d were 257γ in H, 45·3 in D and 195γ in V. Diminution in intensity continued on 12th and 13th and conditions were quiet from 14d 4h to 16d 16h.

After minor disturbance on 17th all elements began to rise after noon on 18th, each having a series of peaks between 15h and 17h, then falling to minima at about 20h. H reached its minimum at 19h 39m after a fall of 220 in 17m, the complete range for the disturbance. Activity then decreased and conditions were quiet on 22nd, continuing mainly so during the rest of the month, despite the existence of a large sunspot, central meridian passage 29.9d in solar latitude -24°*.

JULY - (Average Character Figure 0 - 58)

The first 5 days were quiet and 6th was very quiet. A movement (-5γ , $+59\gamma$ in H; $-\cdot9'$, $+4\cdot5'$ in D; -7γ in V) of 'sudden commencement' type at 7d 21h 9m was followed by only slight disturbance, though H fell 114 γ to a minimum at 8d 7h 50m. A similar 'sudden commencement' movement (-25γ , $+117\gamma$ in H; $-2\cdot2'$, +7' in D and $+1\gamma$, -7γ in V) at 14d 15h 3lm also preceded only a slight increase in activity. The 16th and 17th were quiet and from 18th to 24th disturbance was of insignificant size. At 24d 20h 35m a 'sudden commencement' (-5γ , $+91\gamma$ in H; $-\cdot5'$, +3' in D; -9γ in V) initiated a disturbance which lasted until 26th with ranges of 191 γ in H, 24·5' in D and 140 γ in V. The nearest sunspot was one of central meridian passage 22·0d*

Between 24d 22h and 24d 23h dips in D and V of 13' and 68 γ were associated with a peak of 77 γ in H, and a slightly larger dip in V just after 1h accompanied peaks of 12' and 54 γ in D and H. H and V were both below normal until about 26d 14h but activity decreased and the remainder of the month was almost quiet, the 30th being the quietest day.

AUGUST. - (Average Character Figure 0.58)

Though disturbance of small order was seldom absent, no one period of activity was particularly noteworthy. The quietest periods occurred from 2d 16h to 5d 10h, from 14d 0h to 15d 12h and from 16d 22h to 19d 4h.

At 27d 17h 32m an abrupt movement $(-4\gamma, +46\gamma \text{ in H; } -0\cdot2', +3' \text{ in D; slight in V})$, partially resembling a 'sudden commencement', was followed by about six hours' disturbance which included some rapid oscillations, especially in H. The overall range in H was 135γ .

SEPTEMBER. - (Average Character Figure 0.93)

Except for slight activity during the first 9 hours of 1st and during the night 5-6d, conditions were quiet until late on 9th, when disturbance commenced. Very rapid fluctuations occurred between 1ld 1h and 18h, particularly in H and D, superimposed on variations of greater amplitude which reached a maximum late the same day.

V reached its maximum at 18h 8m, then fell irregularly to a minimum at 12d 0h 50m and still lower at 3h 6m. H, with a rise of 189 γ in 14 minutes, reached the first and highest of 3 sharp maxima at 20h 58m, the others fol-

lowing at intervals of 40 minutes. Deep minima occurred at 11d 23h 12m and 12d 0h 30m. D showed very similar variations, but their amplitude increased after midnight, maxima being reached at 12d 0h 30m and 12d 5h 17m. The ranges of the disturbance were 253y in H. 43.2' in D and 225y in V.

Quieter conditions were experienced from 12d 8h to 14d 18h. A slight disturbance, lasting from 15d 8h to 19d 8h, had no features worthy of note.

After another quiet period activity recommenced at 23d 6h. There was a sunspot whose central meridian passage was at 21.9d*. Hhad sharp peaks of about 160 γ and 120 γ at 13h 20m and 15h 29m, followed by a slow fall and rapid recovery at 24d 2h. The V curve was more regular, with maximum at 23d 18h 47m and minimum just after 24d 2h, when a sharp rise followed. Dhad several peaks between 13h and 18h, then fell slowly to a minimum at 24d0h 40m. A maximum at 2h 12m was followed by a sharp fall. Activity decreased on 24th but was intensified early on 25th, H falling 120 γ to a minimum at 9h 4m and D rising 26' between 2h 25m and 3h 50m. Disturbance continued throughout 25th and 26th, the ranges for the period 23rd to 26th being 273 γ in H, 38.5' in D and 157 γ in V.

There was only minor activity for the remainder of the month until slight disturbance commenced at 30d 8h.

OCTOBER. - (Average Character Figure 0.90)

Slight disturbance on 1st and 2nd - with a 'sudden commencement' type of movement at 2d 17h 20m (-9γ , $+39\gamma$ in H; $-\cdot4'$, $+2\cdot1'$ in D; very slight in V) was followed by quiet conditions from 2d 24h to 6d 24h. A sudden irregular rise of 50y in H and a fall of 12' in D, with rapid recoveries, between 7d Oh and 7d 2h, were followed by only minor disturbances. Phenomena similar in type and magnitude occurred at 10d 17h 50m and 10d 2lh 40m and again on 11th but, though conditions were never quiet, no notable disturbance was observed until 20d 9h. V rose markedly to its afternoon maximum at 15h 14m while H and D fluctuated rapidly with ranges of 100y and 42' respectively. few hours' decrease of activity it intensified again on 21st, D falling rapidly to the lowest value of the year at 18h 12m. The ranges for the days 20th and 21st were 143y in H. 51' in D and 140y in V. A large sunspot in solar lat. + 23° passed the meridian on 21.0d*

The 22nd and 23rd were less disturbed but after a 'sudden commencement' (+8 γ , -25 γ in H; -1.9', +5.2' in D; slight in V) at 24d 6h 39m H fell to a minimum just before noon, then rose with V and D to a maximum at about 15h, each curve showing a triple peak and V reaching its highest value for the year at 15h 4m.

After a quieter day activity was renewed at 25d 19h, D falling rapidly through 22' to a minimum just before 24h. The ranges for 24th and 25th were 185 γ in H, 42·1' in D and 170 γ in V.

The 26th was quiet but a small movement of 'sudden commencement' type (-1.2', +6.2' in D; less definite in H and V) at 27d 3h 46m initiated another disturbance in which movements were very irregular with no outstanding maxima or minima. A large sunspot in solar lat. + 20° passed the central meridian on 26.4d*. Activity diminished on 29th but continued for the remainder of the month.

* "The Observatory" February 1936.

NOVEMBER. - (Average Character Figure 0.47)

Apart from minor activity on the nights 2-3d and 3-4d with slightly more from 5d 2h to 6d 14h, conditions were quiet until late on 1lth. The 12th, 13th and 14th were continuously disturbed but, except for a fall in D through 23' between 22h 30m and 23h 50m on the 12th, there was no noteworthy movement. Ranges for this period were 137γ in H, $38\cdot1'$ in D, 112γ in V.

There were large sunspots in solar lat. -30° and +21° whose times of central meridian passage were 9.5d and 13.2d respectively.*

From 15d 9h conditions were quiet until the evening of 18th when dips of D through 11' and 15' were recorded between 17h and 18h and 23h and 24h respectively, associated with only very slight fluctuations in H and V. Similar dips occurred on 19th and 20th, after which conditions were again quiet until 27d 14h.

After small oscillations V rose rapidly to a maximum just before 20h, simultaneously with minima of H and D. Activity ceased almost immediately but was renewed slightly from 29d 20h to the end of the month.

DECEMBER. - (Average Character Figure 0.74)

The largest sunspot recorded for over seven years passed the central meridian at 2·ld, and another large one on 12·5d,* but except for some slight disturbance on the first 3 days magnetic conditions were mainly quiet till after noon on 14th. V rose rapidly to a maximum at 18h 37m, D fell 17' to a minimum at 22h 40m and H increased rapidly by 113 γ in 38 minutes to its maximum a little later. From 16d 24h conditions were quieter, especially from 21st to 23rd, ranges on the latter day being only 22 γ in H, 3·4' in D and 6 γ in V.

A small 'sudden commencement' type of oscillation at 24d 19h 34m initiated a disturbance in which movements were very irregular but never of large range. Activity decreased on 28th but persisted in a minor way to the end of the year.

167. RSKDALEMUIR: H. (height of barometer clistern above M.S.L.) = 237.5 metres

NOTES ON RAINFAL

1935

+0·6 +0·5

+3.6

+4.6

+5•1

Rainfall Duration.

There were 135 days on which no duration of rainfall was registered. There were 33 days on which the duration of rainfall was registered as 0-1 hour to 1-0 hour, 34 days with 1-1 to 2-0 hours, 80 days with 2-1 to 6-0 hours, 67 days with 6-1 to 12-0 hours, and 15 days with more than 12 hours. The day with the greatest duration was April 16th when the duration was 22-4 hours, the amount falling being 27.4 mm.

Notable falls of the Year. (a) Th

- (a) The greatest amount in a 60-minute period was 10.3 mm, which was recorded between 1h and 2h September 19th. Falls of 5 mm in one hour or less occurred on 19 days; on September 2 this amount fell in 10 minutes.
- (b) Details of the greatest continuous falls are as follows:

Da te	Amount	Duration
	raun.	hrs.
February 20	37	11.0
August 26	27	8•3
August 30	36	11.5
September 18-19	41	7.0
October 7-8	0.0	. 1-9

Wet Periods.

- (a) There were two "rain spells" (i.e. periodε of fifteen or more consecutive days on each of which 0-2 mm or more of rain fell), viz. September 26 October 11, and October 23 November 22.
- (b) There was one "wet spell" (i.e. period of fifteen or mure consecutive days on each of which 1.0 mm or more of rain fell), viz. October £3 November 6.

Dry Periods.

- (a) There were no periods of "absolute drought" (i.e. fifteen or more consecutive days to none of which is credited 0.2 mm of rain or more) or of "pertial drought" (i.e. twenty-nine or more consecutive days, the mean daily rainfall of which does not exceed 0.2 mm).
- (b) There was one "dry spell" (i.e. period of at least 15 consecutive days to none of which is credited 1 mm. of rain or more) viz. May 13 June 1.

Rate of Rainfall (Jardi Recorder).

The highest instantaneous rate of rainfall was 113 mm/hr. at 15h 55h on September 15. The maximum rate exceeded 50 mm/hr. on April 10, June 4 and 11, July 18 and September 2, 3, and 14.

RAINFALL

Amounts in millimetres, for periods of sixty minutes, between the exact hours, Greenwich Mean Time

DURATION OF BRIGHT SUNSHINE
For periods of sixty minutes, between the exact hours of Local Apparent Time

233. ESKDALEMUIR: hg (height of recorder above ground) = 1.5 metres

SEPTEMBER, 1935

SOLAR RADIATION
received on surface
perpendicular to solar beam

Notes. - (1) The initial 2 or 3 of the readings is omitted, i.e., 275-0 is written 75-0.

(2) The minimum refers to the interval from 18h. the previous day to 7h. on the day to which it is entered.

(3) Annual Mean 274-7.

Note: The Potential Gradient is reckoned as positive if the potential increases upwards. For Indeterminate Potential Gradient the following notation is used: Z +, Indeterminate, positive value; Z - , Indeterminate, negative value; Z +, Indeterminate in magnitude and sign.

(a) Mean of all positive readings.

(b) Mean from all complete days using both positive and negative readings.

[§] For explanation see page 181. Q denotes an "International Quiet Day", while D denotes a disturbed day used for the computation of Tables 323 - 334.

Departures from mean of the day adjusted for non-cyclic change.+

Notes .- *Results derived from absolute observations only.

† A local anomaly is known to exist at the site of the observatory.

Godhavn) The values of Inclination and Vertical Intensity depend upon direct measurement of the vertical component of the earth's field.

Abinger)
Lerwick.- A discontinuity occurs at 1934 January 1 in the values of Inclination and Vertical Intensity, owing to an instrumental change.

Ebro, Tortosa.- The values are derived from International Quiet Days only.

Cheltenham. 1935.- The results relate to the seven months January to July.

Mauritius. 1933.- The results relate to the eight months January to August; 1934, to the seven months June to December.

Apia.- 1934 Vertical Intensity. The result relates to the six months July to December; 1935 Declination, to the eight months April to December.

342 REVISED VALUES FOR EARLIER YEARS

INTRODUCTION.

SITE

Valentia Observatory derives its name from the fact that it was originally established on Valentia Island in 1867. It was removed to the mainland in March, 1892, and now lies in a direct line between the old site on Valentia Island and the town of Cahirciveen, about 2 miles (4 km.) northeast from the former, and three-quarters of a mile (1 km.) south-west of the It is quite remote from any other buildings. The general character of the country surrounding the Observatory is hilly. The eastern bank of the Cahir river is about 150 metres to the westward, and in that direction there is no very high ground between the Observatory and the open sea, some $3\frac{1}{2}$ miles (6 km.) away. To the north-west, however, are hills varying in height from 400 (120 m.) to 900 feet (275 m.), the highest being less than 3 miles (5 km.) distant. These are only separated by a narrow gully running in a N N W direction from other hills equally high, which stretch away to the northward: the nearest of these is but little more than a mile $(\frac{1}{2}km.)$ from the Observatory. Beyond the town of Cahirciveen to the north-east the river opens out considerably, and the country in this direction becomes an open boggy basin, rising by only a gentle gradient. Southward of this, however, it soon rises again, and at about amile south-east of the Observatory it culminates in the hill Bentee upwards of 1,245 feet (380 m.) in height. further south it opens out once more to a distance of nearly 5 miles (8 km.)

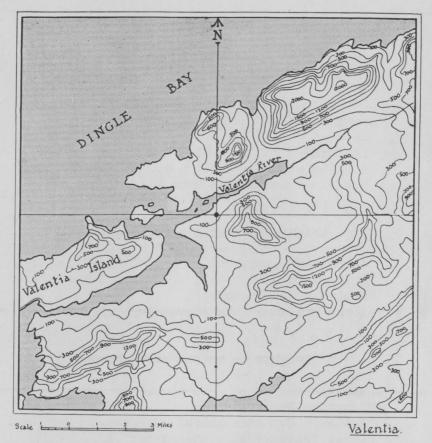

Fig. 15.—Contoured map showing surroundings of valentia observatory. (The heights are given in feet above Irish ordnance datum).

from the Observatory, where there is a range of hills running east and west, and varying in height from 400 (120 m.) to 1,300 feet (400 m.). To the south-west there is an opening to the sea, between Valentia Island and the mainland; and the circle of hils is completed by those on the island itself, the highest of which is about 800 feet (240 m.) high, and bears about west-south-west from the Observatory. A contoured map of the surroundings, a general view from South, a site plan and a view showing the disposition of the various instruments are reproduced in Figs. 15-18.

METEOROLOGY

The elements dealt with in the following tables are: atmospheric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, earth temperature, minimum temperature on the grass, together with a diary of cloud, visibility and weather.

Pressure and Temperature. The photographic barograph and thermograph are installed in a room on the ground floor of the Observatory tower. The standard Fortin barometer, from which the control readings at 9h. 15h. and 2lh. are taken, is mounted in the same room beside a window which faces the north-east. The stems of the dry and wet bulb thermometers pass out into the screen placed against the north wall of the tower. Close to the bulbs of these thermometers are the bulbs of the standard thermometers from which the control readings at 9h. 15h. and 2lh. are taken.

Rainfall. - The Beckley rain-gauge and 8-inch (20.3 cm.) check gauge are placed in a railed-off enclosure about 40 metres to the north of the tower.

Sunshine. The recorder is cemented to a wooden rail on the roof of the tower. The exposure of the sunshine recorder is such that there is no appreciable loss of record due to obstructions in the months of May, June, July and August. During the remainder of the year the hill Bentee lying to the south-east cuts off early morning sunshine. The reduction in possible record, assuming that the recorder becomes sensitive to sunshine only when the sun is at an altitude of more than three degrees, is shown in the following table for the 1st and 15th of each month:-

I	Reduction in Possible Record in Tenths of an Hour.												
Month.	Jan.	Feb.	Mar.	Apr.	Sept.	Oct.	Nov.	Dec.					
1st 15th	hr. •5 •6	hr. •5 •5	hr. •7 •7	hr. •5 •3	hr. •3 •5	hr. •7 •7	hr. •5 •5	hr. •6 •5					

Wind, Speed and Direction. Up to 1925 measurements of wind speed and direction as given in tables 413-424, were obtained from the Robinson cup anemograph on the roof of the Observatory tower. From 1926 to 1931 measurements of wind speed and direction refer to records from an old pattern Dines Pressure Tube Anemometer. A comparison between the mean velocities as recorded

by this anemometer and the cup anemograph is given in the General Introduction. A new Dines Pressure Tube Anemometer with 1 -inch connecting pipes, was brought into use as from January 1st 1932. The new instrument was erected alongside the old instrument with its head at the same height: a comparison extending over the period May, 1931, to January, 1932, showed that the new instrument recorded higher velocities than the old. In hourly mean values the difference was nearly uniform and equal to ·4 m/s or 1 mi/hr. In gust velocities the increase was approximately 12 per cent of the velocity recorded by the old instrument.

The site of the Dines Pressure Tube Anemometer is in an open field, about 250 metres S E by E of the Observatory tower. About 1 mile ($l_2^{\frac{1}{2}}$ km.) to the south-east is the highest point (1,245 feet) of the hill Bentee which extends for some little distance in a northerly and south-westerly direction. A description of the surrounding country has already been given.

In a few instances where records of the Dines Pressure Tube Anemometers have been defective, the required values have been obtained from the records of the cup anemograph, a suitable adjustment of such values having been made in accordance with the table in the General Introduction showing the effect of exposure on the two instruments. Values thus obtained are entered as interpolated values.

<u>Farth Temperature.</u> The thermometers are at depths of 30 cm. and 122 cm. below the grass covered surface of the ground. The site is well exposed. The thermometers are of the standard type described in the "Meteorological Observers' Handbook",

Minimum Temperature on the Grass. The grass minimum thermometer is of the type described in the General Introduction. It is exposed over short grass in the field enclosure. It is set at 18h and read at 7h on the succeeding day, the observation being entered to the day of reading.

<u>Visibility</u>.- Lists of the objects used for visibility observations and their distances and bearings from the point of observation are given in the following tables.

Bearing

1	30,000	-	•	No object available. (Croagh-marhin well visible.)
m	50,000	-	•	No object available. (Croagh-marhin exceptionally visible.)

Two observations, one in a landwards direction, the other in a seawards direction, are made at each hour of observation. The position of the Observatory is such that a distinction between visibility landwards and seawards cannot be made when the range of visibility is less than 1,000 yards. Objects corresponding with the letter A to E have therefore been included in the table of landwards objects only. Kilkeaveragh Mountain is used as both a landwards and seawards object corresponding with J.

Entries of "1" and "m" for visibility in a landwards direction are made:-

- (a) When Croaghmarhin Mountain (see table of seawards objects) is clearly visible and there is reason to believe that the range of visibility in a landwards direction is as good as, or nearly as good as, visibility seawards.
- (b) When Croaghmarhin Mountain is invisible but there is reason to believe from the appearance of Drung Hill that the range of visibility landwards is greater than the range seawards and is sufficiently good to justify the entry made.

When the mountains used as objects at 3,500 metres and beyond are cloud capped the appropriate entries for the range of visibility are determined by the clearness or otherwise with which the lower parts of the mountains can be seen.

The Observatory is far removed from smoky industrial areas; the observations are therefore not much affected by smoke pollution of the atmosphere.

Notes on the Meteorological Summaries.

The Weather of 1935. Generally, the weather was variable with rainfall below normal and sunshine and temperature above the average. January, March, July and December were notably dry and June and November abnormally wet.

<u>Pressure.-</u> No change in the values used for reducing pressure at station level to pressure at mean sea level was made at Valentia Observatory by the introduction in 1928 of the revised scheme as set out in the General Introduction.

Mean Pressure for the year was 0.8 millibars below normal. Of the monthly mean pressures five were higher and seven were lower than normal. The departures ranged from an excess of fifteen millibars in January to a deficiency of eleven millibars in November.

Details of the Fourier analysis of the diurnal inequalities of pressure for the year are given in Table A, together with normal values referring to the period 1871-1926 as computed by Dr.A.Crichton Mitchell.* The coefficients are given to the nearest ·Ol mb. and the phase angles to the nearest lo.

Temperature.- Mean temperature for the year 1935 was 0.50A.(0.90F.) above normal. For the individual months, March, with an excess of 2.60A.(4.70F.) and December with a deficiency of corresponding amount showed the greatest departures.

^{*}Diurnal Variation of Pressure and Temperature at Cahirciveen (Valentia) by A.Crichton Mitchell D.Sc., 1871-1926. Q.J.R. Met. Soc. 1929. p.310.

The harmonic analysis of the monthly and seasonal diurnal inequalities of temperature is given in Table B. together with normal values referring to the period 1871-1926 as computed by Dr.A.Crichton Mitchell.* The coefficients are given to the nearest \cdot 01°A and the phase angles to the nearest 1° .

Rainfall. - The total rainfall for the year was 1304 mm., this amount being 110 mm. below the normal. A record dry January (27 mm.) and a record wet June were notable contributions to a variable year.

Bright Sunshine. - Sunshine was slightly in excess of normal the increase reaching 35% in May. May with a total of 256 hours (53% of possible) was the brightest and January with 37 hours (15% of possible) the dullest month.

Cloud and Weather. The mean amount of cloud at all observation hours was 7.5. The most cloudy month was January with mean cloud amount of 8.5. The month with least cloud was May with a mean of 5.7.

<u>Visibility</u>.- The observations of visibility in tables 429-440 refer to visibility in a landwards direction. The observations, when the range of visibility seawards differs from the range landwards, are shown in the following tables:-

TERRESTRIAL MAGNETISM

Notes on the Magnetic Observations for the year 1935.

Absolute observations of declination, horizontal force and inclination were made weekly at Valentia Observatory during the year 1935. The instruments in use were Dover unifilar, No. 139, with collimator magnet 139A mirror magnet 139C, and Dover dip circle, No. 118. These instruments are the same as in previous years except that Dover dip circle, No. 239 was used from May 1930 to October 1931. The mean times of observations were 10.23 for declination, 11.42 for horizontal force and 14.30 for inclination, all according to Greenwich Mean Time. In the individual observations the greatest departure from the mean time in any element was 10 minutes. The deflection of the mirror magnet was measured for two distances of the collimator magnet, The complete deflection observation consisted of namely, 30 cm. and 40 cm. eight readings of the mirror magnet. The distribution constant, P, used for 1935 was computed from the mean deflections for 30 cm. and 40 cm. for the seven years 1928-1934 inclusive. The mean P so obtained was 7.53. The moment of the collimator magnet has decreased at the rate of about 1 unit per annum.

The values of declination, horizontal force and inclination obtained in the absolute observations are given in detail in Table C, but in Table D the mean monthly values are computed only from such of these absolute observations as were taken at times subsequently found, by reference to the Eskdalemuir magnetograph curves, to be free from serious disturbance. Observations in Table C taken at disturbed times, and not, therefore, utilised for mean values in Table D, are marked with an asterisk. The north, west and vertical components and the total force for each month and the year are computed from the corresponding mean values of the observed elements.

Westerly declination has diminished by 11.0 as compared with 1934. From 1933 to 1934 the decrease was 10.8 and in the previous 12 months 10.9. The average annual decrease for five year periods since 1910 is as follows:-

1910-15 1915-20 1920-25 1925-30 1930-35 8'2 9'2 11'1 11'0 10'-7

The rate of the eastward movement of the magnetic needle increased slowly up to about 1927, but is now apparently decreasing again.

Northerly inclination decreased 0'1 from 1934 to 1935. Changes during the past few years have been irregular but, on the whole, it appears that inclination is diminishing at a slow rate.

Up to 1920 the mean annual values of horizontal force had shown a steady decline from year to year. In the years 1921 to 1924, 1927, 1931, 1933 and in 1934 the change was in the opposite direction, each year having a mean value higher than that of the preceding year.

The a	\mathtt{amount}	of	annual	change	is	shown	in	the	following	table:-
-------	-------------------	----	--------	--------	----	-------	----	-----	-----------	---------

Period	Annual Change.
1910-15	5γ decrease (Mean Value)
1915-20	6γ " (Mean Value)
1920-25	2γ increase (Mean Value)
1925-26	14γ decrease
1926-27	2γ increase
1927-28	llγ decrease
1928-29	5γ "
1929-30	8y #
1930-31	2γ increase
1931-32	6γ decrease
1932-33	2γ increase
1933-34	ly "
1934-35	8y decrease

The reversal of the annual change in horizontal force in certain years was not accompanied by a corresponding reversal in total force. The average annual decrease in total force for five year periods since 1910 is as follows

1910-15 1915-20 1920-25 1925-30 1930-35 49 γ 33 γ 32 γ 20 γ 22 γ

Total force which until 1934 had continued to decrease but at an apparently diminishing rate, has this year shown an increase of 6γ . This is the first time an increase has been recorded. The individual changes from year to year as shown in Table D are somewhat irregular, but this may be due in considerable measure to instrumental uncertainties. The total force is computed from the horizontal force and the inclination, using the formula T=H

sec. I, so that an error of 0.1 in I would give an error approximately 47 in T at Valentia. In addition, it is to be remembered that the secular change data for Valentia are obtained from absolute observations made at fixed hours at any of which the value obtained for an element may differ, by an amount which is not necessarily constant, from its true mean value for the day of observation. It is by no means improbable that owing to this and errors of observation, uncertainties to the extent of several tenths of a minute of arc may be introduced into the mean value of I for the year. For the average change over a series of years these possible errors are naturally much diminished and the average fall of 33y per annum in the total force obtained from the values in Table D is probably a close approximation to the true change. This continued decrease in the total force indicates that the rise in value of the horizontal force observed in certain years was not a true crease in the magnetic field but merely a component increase arising from the fall in the inclination, which becomes proportionately more effective in the horizontal component as the actual inclination angle itself becomes smaller. The magnetic field in the Valentia district continues to become less year by year, therefore, although, without observations of inclination, the opposite would have appeared to be the case in some years.

NOTES ON RAINFALL

388. VALENTIA OBSERVATORY

1935

Notable Falls of the Year: -

There was no "Noteworthy Fall" during the year. The maximum hourly value was 10 mm which fell from 11h to 12h on June 26th. The maximum daily value was 38 mm on June 26th.

Details of the greatest continuous falls are as follows:-

Date	Amount	Duration
	mm	hrs
Feb. 26th.	29	7•2
June 22nd.	28	12.3
June 26th.	38	15.3
Nov. 11th.	20	7.9

Wet Periods: -

There were 4 "Rain Spells" (i.e., periods of 15 or more consecutive days on each of which 0.2 mm or more of rain fell) April 4th to 22nd, June 1st to 15th, Sept. 8th - 24th and Sept.28th - Oct 13th, and 2 "Wet Spells" (i.e. periods of 15 or more consecutive days on each of which 1 mm or more of rain fell) - Feb. 18th - Mar.5th and Oct.29th - Nov 20th.

Dry Periods: -

There was no occurrence of an "Absolute Drought", Partial Drought or Dry Spell during 1935.

Rate of Rainfall (Jardi Recorder)

The highest instantaneous rate of rainfall was 124 mm/hr at 02h 14m on August 21st. The maximum rate exceeded 50mm/hr on 32 days.

RAINFALL

Amounts in millimetres, for periods of sixty minutes between the exact hours, Greenwich Mean Time
389. VALENTIA OBSERVATORY: H_r (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + h_r (height
of receiving surface above ground) = 9·1 metres + 0·5 metre

RAINFALL

Amounts in millimetres, for periods of sixty minutes between the exact hours, Greenwich Mean Time.

399. VALENTIA OBSERVATORY: Hr (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + hr (height of receiving surface above ground) = 9.1 metres + 0.5 metre.

WIND: DIRECTION AND SPEED

Direction expressed in degrees from North (E = 90°, S = 180°, W = 270°, N = 360°): Speed in metres per second

417. VALENTIA OBSERVATORY:

Dines Pressure Tube Anemometer from January, 1926

H_a (height of anemometer above M.S.L.) = Height of ground above

0.53

Dines Pressure Tube Anemometer

Beckley Raingauge Rim

The observatory was built in 1769 as the private observatory of George III. Since 1842 it has been devoted to physics and meteorology. The meteorological records are continuous from 1854. The Observatory is in the Old Deer Park, Richmond (Surrey), about 10 miles (16 km.) to the west of the City of London. The Observatory stands on a low artificial mound whose level is about  $1\frac{1}{2}$  metres higher than that of the surrounding park. Round the Observatory a golf course has been laid out. The River Thames is distant about 300 metres on the north and west. Kew Gardens, which are extensively wooded, lie to the east-north-east, the nearest point of the Gardens being about 600 metres away. The town of Richmond, to the south-east, is about 1,100 metres distant. On the east side of the Park is the main road from Richmond to Kew; on the south side the railway from Richmond to Twickenham. An open area partly wooded, Syon Park, lies to the north-north-east across the river. Richmond Park is about  $1\frac{1}{2}$  miles  $(2\frac{1}{2}$  km.) to the south-east. A general view of the Observatory building and the exposure lawn, an aerial photograph, a plan of the surrounding country and a site plan are to be found in this volume. The photographs were taken in 1935. For the early history of the Observa-

#### METEOROLOGY.

The elements dealt with in the following tables are: atmospheric pressure, temperature, humidity, rainfall, sunshine, solar radiation, wind speed and direction, earth temperature, minimum temperature on the grass, level of underground water; there is also a diary of cloud and weather.

For brief descriptions of most of the instruments from which values of the above elements have been obtained and of the methods of tabulating the records, reference should be made to the General Introduction. The following notes supplement, where necessary, the information contained therein.

#### Notes on Instruments.

Pressure .- The barograph is mounted in the basement of the Observatory, where the diurnal variation of temperature is very small. The normal position of the instrument has been in the north room occupied by the magneto-When the magnetographs were removed and the preparations for the installation of the seismographs were commenced, the barograph was placed in the photographic darkroom (June 16th, 1925). The instrument remained in that position until May 21st, 1928, when it was restored to its original site and electric lighting installed. The barograph magnifies barometric changes in the ratio 1.553: 1, i.e., the change of ordinate equivalent to a change of 1 mm. in the height of the barometer is 1.553 mm. "Residual corrections." obtained from the control observations taken daily with the Newman Barometer at 9h, 15h and 2lh, are applied to the hourly measurements. The same correction is applied to all the readings on the same photographic sheet, i.e., generally for forty-eight hours. The individual entries published for the hours of the control observations may differ by -3 mb from those observations. The Newman barometer is compared from time to time with the two large mercury barometers, which were set up in 1855 and 1860 respectively, the accuracy of which has been confirmed by indirect comparisons with the new standard of the N.P.I.** A zero correction for the Newman barometer is based on these The correction +  $C \cdot 2$  mb. (+ $\cdot$ 006 mercury inch) which has been comparisons. applied for many years, remained in use. Comparisons are made on the assumption that the value of the acceleration due to gravity is  $g = 981 \cdot 199 \text{ cm/sec}^2$ . This is the value given by pendulum observations. ††

^{**}London Met. Mag., 68, 1933, pp.119-120.

tht comparison between the values of "g" at Cambridge and Kew Observatory was made during the year 1925 by Sir G.P. Lenox-Conyngham with the assistance of Mr. G. Manley. A similar comparison between Potsdam and Cambridge was made by Prof. Meinesz earlier in the year. These observations are in accord with those made at Kew and Potsdam by Putnam in 1900, from which the value stated above was derived. The value for Potsdam, g = 981.274, based on the observations of Kühnen and Fürtwangler, is adopted as the standard of reference. For the latitude of Kew Observatory, 51° 28', the formula in the General Introduction gives g = 981.185.

The departure from the value given for the latitude by the formula quoted in the General Introduction is insignificant. On occasions when a loss of trace occurred, the missing hourly values were derived from the Dines Float Barograph.* There were 20 hours in the year for which this was necessary.

Temperature and Humidity. - The thermograph is mounted in the West Room on the first floor of the Observatory, the thermometer bulbs being exposed in the screen attached to the north wall of the building. This screen has single louvres and the bottom is open. There is an additional flat louvred screen which shields the main screen from direct sunshine when the sun is in the West and not too low. The height of the bottom of the bulbs of the recording thermometers above the bottom of the sides of the screen containing them is 30 cm. in summer, 33 cm. in winter. The height of the bulbs above the top of the artificial mound on which the Observatory stands is approximately 3 metres; the height above the lawn where the rain-gauge is situated is approximately 5 metres. The scale values of the photographic records are not identical for the dry and wet-bulb curves. For the dry-bulb, tube No. 4 II was in use and the scale value was 1 mm. = 0.3336°A; for the wet-bulb, the old Falmouth wet-bulb tube (no number) was in use and the scale value was 1 mm. = 0.290°A.

Up to the year 1916 thermometers graduated on the Fahrenheit scale were in use in the North Wall Screen for controlling the thermograph readings. Then thermometers graduated in the absolute scale were introduced. Of these two absolute thermometers one was broken in June, 1933 and one of the old Fahrenheit thermometers took its place. Readings of the control thermometers are used for the daily weather service and for that purpose readings on the absolute scale have to be converted to Fahrenheit. It was decided that it would be more convenient to make the alternative conversion from Fahrenheit to Absolute and accordingly the use of thermometers with the absolute graduation terminated at the end of 1933. Before the Fahrenheit thermometers which had been in use up to 1916 were put back in the screen they were tested at the National Physical Laboratory. It is satisfactory to note that the two thermometers are correct within 0-1 of. The close agreement of the scale of the Kew standards with the scale of the hydrogen thermometer was demonstrated by Harker in 1905**. The recent tests indicate that these thermometers with large bulbs keep their zeros well.

The water for the wet-bulb thermometers is supplied from a tank fitted outside the screen. A large bottle is inverted over the tank and water flowing from this bottle keeps the level constant in the tank and in the cups from which wicks are taken to the wet-bulbs. The height of the apparatus is adjusted so that the water drips steadily from the wet-bulbs. A bottleful of water lasts at least a week. It is found that the bottle survives severe frost.

Control eye-readings of the standard thermometers are taken daily at 9h, 15h and 2lh. Residual corrections obtained from the control observations are applied to the hourly measurements of the curves. The same correction is applied to all the readings on the same photographic sheet, i.e., generally for forty-eight hours. The individual entries published for the hours of the control observations may differ by 0.3°A. from these observations. The larger departures refer to occasions when temperature is oscillating or changing rapidly.

Phys. Lab., 2, p.215.

^{*}For descriptions of this instrument see "Observatories' Year Book",1923p.94, and London, Quart. J. R. Met. Soc., 55, 1929, p.37.

**London Proc. Roy. Soc. 78 (A), 1907, p.225. and London, Coll. Res. Nat.

In cases of loss of the dry-bulb record owing to the failure of the electric light or any other cause the readings of a mercury in steel thermograph are adopted. The photo-thermograph was completely overhauled between May 20th and 25th; during this period the mercury in steel thermograph was temporarily housed in a second North Wall Screen.

When the wet-bulb trace is missing or defective the missing values are derived from the dry-bulb trace and the records of a hair hygrograph. The same procedure is always adopted when the wet-bulb reading is below 273°A. 464 hours had thus to be dealt with during the year. Humidity was determined from the dry and wet-bulb readings by the procedure described in the General Introduction to this volume.*

It may be noted that during 1935, as in previous years, the temperatures published for Kew Observatory in the Daily Weather Report and elsewhere also refer to the North Wall Screen. For the daily and weekly reports the readings of maximum and minimum thermometers exposed in that screen are utilised.

Rainfall.- As from January, 1921, the standard raingauge for the Observatory has been an 8-inch gauge with the deep "Snowdon" funnel. The site is level and protected from wind, principally by hedges about  $1\frac{1}{2}$  m. high and distant 11 metres to East and 17 metres to West. The readings of this standard gauge are at 7h and 18h. The hourly readings of the Beckley gauge are adjusted to give totals in agreement with the standard gauge. Continuous records of the rate of rainfall are obtained from the Jardi rate of rainfall recorder. The instrument is situated 12 metres from the north wall of the Observatory and the rim is 1.2 metres above the surrounding ground. With heavy rainfall comparable records are obtained from the "minute-by-minute gauge"  $\ddagger$ . The rim of this gauge which is situated on the lawn 10 metres SW of the Beckley gauge is 1.2 metres above the ground.

Sunshine.— The sunshine recorder is mounted on the south parapet of the roof. The same frame has been in use since 1880 and it is believed that the ball has not been changed. The ball is now somewhat yellow. The exposure is satisfactory. The greatest elevations of the sky line in the azimuths in which the sun can rise and set are 1° and 3° respectively.

Solar Radiation. For previous years observations made with the Angstrom pyrheliometer of the intensity of direct solar radiation received by a surface normal to the sun's rays have been published in the Year Book. From 1934 these observations have been supplemented by daily totals of radiation recorded by the Gorczynski pyrheliograph. The Angstrom pyrheliometer observations are made within half an hour of noon. The mean intensity, derived from three readings, is given in Tables 499 to 510 in mw/cm².(1 mw = 0.01435 cal/min.). The secant of the sun's zenith distance at the time of these observations is entered under "sec Z" and the atmospheric conditions under "sky"

The Angström instruments in use are by Rose, Stockholm. No. 24 was in use throughout the year. The ammeter is No. 68956, which was certified at the National Physical Laboratory in 1919.† The readings are evaluated according to Angström's original instructions.†† To bring the readings into

^{*}Prior to 1926 the tables, based on Glaisher's factors, published in "The Computer's Handbook," M.O. 223, Sec. 1, 1916, were used.

^{##} London, Met. Mag. Aug. 1934., pp. 157-158.

tIn view of the discovery by Marten (Berlin, Ber. Meteor. Inst., 1928, p.64) that errors are likely to be caused by temperature changes produced in a microammeter when sunshine falls on it, it may be noted that the instrument used at Kew is always in shadow.

ttLondon, Report of the International Meteorological Committee, St. Petersburg, 1899, p.57.

accordance with the scale adopted by the Smithsonian Institution, a correction of + 3.5 per cent. would be required. ‡

The Moll thermopile of the Gorczynski pyrheliograph is mounted on a heliostat near the sunshine recorder and is connected to a Richard millivoltmeter in the dome. The pen of the millivoltmeter is depressed once each minute electromagnetically. The apparatus is standardised by the Angström pyrheliometer. The total radiation for the day is given in joules/cm² (ligule = .239 calorie).

#### Wind Speed and Direction .-

Particulars of Dines Pressure Tube Anemometer:-

Pattern .. .. Mark II (see "Observer's Handbook" 1934 p.115).

Suction Holes .. .. 80 holes in 4 rows of 20. Diameter 2 mm.

Connecting tubes .. .. Length 8 m. Internal diameter 24 mm.

Height of vane above lawn 23 m.

The present instrument with its head mounted above the dome has been in regular use since January 1st 1931. Details of the anemometers previously in use will be found in the 1933 Year Book.

There is a continuous belt of trees along the river about 300 metres away and other tall trees at shorter distances, but few of the trees have their summits above the level of the new vane.

Earth Temperature.— The two thermometers in use were at 30 cm. and 122 cm. The ground in which the tubes for the thermometers are sunk is under grass. The soil is gravel. The site is well exposed. There are, however, three fruit trees about 9 metres to the east and 6 metres high. The bulb of the lower thermometer is 430 cm. above sea level. In some years the underground water surpasses this level.

Minimum Temperature on the Grass. The grass minimum thermometer is set at 18h and read at 7h on the succeeding day, the reading being assigned to the day of reading.* The thermometer is placed with the bulb about 25 mm. above the turf. The exposure is good, there being no obstruction within 76° from the zenith. The thermometer has a spherical bulb, diameter 17 mm.

^{*}R.E. Watson, London, Met. Off., Geophys. Mem., 3, No. 21, 1923.

*The hour of the readings to be published in the "Observatories' Year Book" was changed from 9h. to 7h. as from January 1st, 1924.

#### Notes on Meteorological Tables.

The year was warm, especially in the summer months.

The lowest reading of the "grass minimum" thermometer was 261.10A (10.6 °F) on Dec. 22nd.

The lowest temperature in the North Wall Screen, 268.9 A (24.6°F) was recorded between 8h. and 9h. on Dec. 23rd.

Dec. 23rd was an "ice day" the maximum temperature in the North Wall Screen being 271.80A (29.80F).

The maximum temperature in the same screen was 302.50A (85.10F) on July 14th.

There were 14 days on which the maximum temperature exceeded  $300^{\circ}$  A(80.6 °F).

The rainfall for the year was 7% above the normal.

The heaviest fall occurred on July 2nd, 28 mm.

The sunshine for the year, 1511 hours was 46 hours in excess of the normal.

The excess was greatest in July.

The highest wind velocity recorded in a gust was 31 m/s (69 mi/hr) on Sept. 17th.

Diurnal Variation of Pressure and Temperature. Harmonic Analysis. The first four harmonic components computed for each month, for the year and for each of the three seasons Winter, Equinox and Summer are set out in Tables A and B. In these tables the c's are the amplitudes of the component sine waves, the angles  $\alpha$  are the phases of the waves at midnight so that if t is the time in hours since midnight the inequality is given by the expression  $c_1 \sin (15t^0 + \alpha_1) + c_2 \sin (30t^0 + \alpha_2) + \dots$ 

The curves are tabulated according to Greenwich mean time but the phases have been reduced to local mean time. The difference in longitude between Kew and Greenwich being only 19' the correction is hardly appreciable in the figures, which are rounded to the nearest degree.

The "normals" refer to the years 1871-1926 and are based on Dr. Crichton-Mitchell's calculations*. It should be mentioned that in the tables published by Dr. Mitchell the phases were with reference to local apparent time. In the Observatories' Year Book 1934 the distinction was overlooked.

.

Level of Underground Water .- In Table 527 there is given for each day the height of the surface of underground water. Up to August 1933 the level recorded was that of the surface of the water in a pipe passing through the From August 17th 1933 to December 20th 1934 the floor of the basement. float rested on the bottom of the well, the water being lower than at any previous time since the installation of the apparatus. From November 1933 to December 1934 observations were made on the site of a pump in the garden, about 25 metres west of the well in the basement. The zero of the scale of height is at the same level as that of the well in the basement. According to measurements made in January 1935 the height of the bench-mark above this zero was 75% cm2. The height of the bench-mark, which is on the east wall of the observatory, above the (Newlyn) datum of the Ordnance Survey was determined in 1932 as 23.245 feet = 763 cm. Accordingly the height of the zero Ordnance datum is 13 cm. In 1935 the well in the basement was used except during the period Aug. 23rd-Oct. 3rd when it was again dry.

<u>Cloud Amount.</u> - The mean cloud amounts for the six hours of observation are given month by month in the diary of cloud and weather. The following means are derived from these data:-

Mean Amount of Cloud from Six Observation Hours.

Month	Jan.	Feb.	Mar.	Apl.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year

Mean Amount of Cloud for the Year at the Six Observation Hours.

Hour	7h	9h	13h	15h	18h	21h
Cloud	7-1	7•5	. 7-8	7•5	6 • 7	5•9

<u>Visibility.-</u> The objects used for the classification of visibility are enumerated below. The Observatory is on very low ground. The view is bounded on the south-east by Richmond Hill and on the west by the trees near the river. For object H a church tower seen through trees and with high ground behind it has to be used. There is no conspicuous object at the appropriate distance to serve as I, and interpolation is necessary. The object J is in London and is therefore more affected by atmospheric pollution than the other objects.

#### ATMOSPHERIC ELECTRICITY

In Atmospheric Electricity the systematic observations reported in the Year Book are devoted to potential gradient, air-earth current and conductivity. These three elements are observed each afternoon when conditions are favourable. In the case of potential gradient the continuous autographic records are also utilised.

Potential Gradient, Conductivity and Air-Earth Current. Since 1909 and current flowing from air to earth has been estimated by the method developed by C.T.R. Wilson.* Until the end of 1930 the observations incorporated in the Year Book were made with an electrometer set up on a tripod. The current received by a small plate mounted on the electrometer was measured, as well as the strength of the electric field over this plate. From these measurements the effective conductivity of the air was deduced and hence the strength of the current in the natural electric field.

It was always realised that this scheme was not entirely satisfactory. The improvement. construction of an underground laboratory has facilitated an The current which is now measured is that flowing into a plate which is flush with the roof of the laboratory and nearly at ground level. supported from below on a stand which carries a Lindemann electrometer and a variable condenser or "compensator". The cover for the plate is mounted on a long handle which can be manipulated from below. A detailed description of the installation has been published in a Geophysical Memoirt prepared by Mr. F. J. Scrase. The electrometer is calibrated once a month by means of Weston standard cells. Since the beginning of 1932 absolute measurements on fine afternoons at 14h 30m of potential gradient, air-earth current and conductivity have all been made with this apparatus.

The potential gradient, F, is given in volts per centimetre by the formula,  $F = 4 \pi \left( 9 x 10^{11} \right) \text{ Cv/A},$ 

where C is the capacity, in farads, of the system (when shielded,) v the voltage acquired by the test plate after being exposed to the field, earthed and then shielded, and A is the area of the plate. A minor alteration was made to the apparatus on 11th October 1933 when a shutter was fitted to the electrometer system so that the latter can be completely screened from the compensator whilst readings are being made. This involved a slight change in the capacity from 6.00 to  $5.91 \times 10^{-11}$  farads. The diameter of the test plate is 20.8 cm. The mean strength of the electric field is derived from five observations made at intervals of about 6 minutes.

The air-earth current is given in amperes per square centimetre by the formula,

$$i = C\delta v/At$$

where  $\delta v$  is the voltage acquired by the plate in t seconds. For obtaining the mean value of the current four observations, each lasting five minutes, are averaged. The observations of the current are sandwiched between the observations of the field strength and from the two mean values i and F the conductivity  $\lambda +$  is deduced. No observations are made during rain nor

when the potential gradient is negative.

The use of the testplate at ground level introduced a discontinuity in the series of observations. Revised mean values for the period up to 1931 have been published in Mr. Scrase's memoir. In 1935 the mean value of the current for the year, allowing equal weight to each month is  $112 \times 10^{18}$  amp. cm.² This is somewhat higher than the corresponding values for other years, the mean value for the period 1912 to 1934 being  $100 \times 10^{18}$  amp. cm.² The mean value of the conductivity for the year is  $38 \times 10^{18}$  ohm.¹ cm.¹ whilst the mean of corresponding values for the period 1912 to 1934 is  $37 \times 10^{19}$  ohm.¹ cm.²

<u>Potential Gradient</u>. - Two changes in the system by which potential gradient is estimated were made in 1932.

The Kelvin electrograph, which has been housed since 1915 in a low building known as the Clinical House, provides a record of the electrical potential at a point not far from the wall of the building. By the application of a factor the potential gradient at a specified site is deduced.

Up to Feb. 10th, 1932 the point at which the potential was measured was where the jet from a water dropper broke into spray. On that date a radio-active collector was substituted for the water dropper. The collector is 1.21 m. from the window and 1.87 m. above ground level. A collector freshly coated with polonium is now installed every six months. The adoption of the radio-active collector in place of the water dropper eliminates the risk of failure of the apparatus owing to frost.

The second change of practice was in the system adopted for standardization. Previously the absolute observations were made at a site in the Observatory garden, the potential at points one metre and two metres above the ground being determined with the aid of a lighted fuse carried by a long insulated rod and connected to an electrostatic voltmeter.

As from the beginning of 1932 the electrograph has been standardized by means of the observations of the field strength over the test plate of the Wilson apparatus at the underground laboratory. Experiments have shewn that the potential gradient found in this way is, to a very close approximation, equal to that found by measuring the potential at a height of one metre in the open part of the grounds.

Owing to this change of practice there is a discontinuity in the published record of potential gradient. Amended values of the monthly and annual means of potential gradient for earlier years have been published in Mr. Scrase's memoir. The amended figures represent more closely the potential gradient in the open. The correction to be applied was + 12 per cent.

The control observations are now taken at 14h 30m. From the observations the factor is derived by which the potential gradient recorded by the electrograph must be multiplied to obtain the potential gradient in the open.

The mean factor for the year was 2.73. The equivalent height of the collector of the electrograph may be estimated by dividing one metre by this factor, i.e., the collector was on the average at the same potential as a point 36.6 cm. above ground in the paddock.

The data appearing in Table 541 include the electrical character figure assigned to each day from the consideration of the electrograms. Of the character figures, 0 denotes the absence of negative potential, 1 implies the existence of negative potential at one or more times during the day but with a total duration of less than 3 hours, while 2 implies the existence of negative potential with a total duration of 3 hours or more. As a negative potential gradient hardly ever occurs except when rain is in the neighbourhood, character 0 occurs on dry days and character 2 on days with continuous rainfall. The present criteria for character figures were adopted as from the beginning of 1914. Correcting for missing days, the average frequency of character figure 0, 1, and 2 during the years 1914-1934 inclusive were 185: 138: 41. The corresponding figures for 1935 are 141: 161: 63.

In accordance with a resolution of the International Union for Goedesy and Geophysics (Section for Terrestrial Magnetism and Atmospheric Electricity: Prague Meeting 1927) tabulations of the duration of negative potential gradient have been included in the Year Book since 1928. The total duration of negative gradient is given for each day for which the electrograph record is satisfactory.

Table 542 contains daily data derived from measurements of the electro-They represent means for the 60-minute intervals ending at 3h, 15h and 21h G.M.T. respectively. On occasions when the trace was defective, either through failure of insulation or some other cause, values of potential gradient have been omitted. The electrograph is intended to record the potential gradient of fine weather and the limits are approximately -1500 and +2000 volts per metre. In showers and thunderstorms gradients of 10000 volts more may occur. These are, of course, beyond the range of the Even when the curve does not go beyond the limits of the chart per metre or more may occur. instrument. the changes may be so rapid that no satisfactory estimate is possible of the mean value of the ordinate. All such occurrences are indicated by the letter If there is no doubt as to the sign of the hourly mean value, though a numerical measure is unobtainable, the sign is indicated by a + or a - attach-The symbol zt indicates that there were oscillations on both ed to the z. sides of the zero lines, and that the sign of the mean value was uncertain.

The extreme hourly values in Table 542 are 1255v/m at 9h on Dec.17th and -1310 at 3h on Apr. 7th. The former value is representative of foggy conditions. The extreme negative gradient was associated with moderate rain.

At the foot of each section of Table 542 there are two sets of mean values. These are obtained according to different rules. The (a) mean is the arithmetic mean of all the positive potential gradients in the column. The (b) mean is the algebraic mean of all the entries which remain in the column after those have been eliminated which refer to days in which at least one of the four hourly values is indeterminate. The last line gives the mean value for each month as derived from the (a) and (b) means for the four hours.

The diurnal inequalities and the mean monthly and annual values in Table 543 are based on the curves for certain "quiet days". Normally 10 quiet days are selected in each month, these being calendar days characterised by no negative potential gradient, no large irregular movements, no indication of inferior insulation and no large non-cyclic change. When there

are not 10 calendar days with these characteristics in a month the number can sometimes be made up by using other spells of 24 hours. In 1935 as in 1934 there were numerous occasions when negative potential gradient occurred in fine weather. This phenomenon, which has not yet been explained, happened with wind from North-East and mostly at night. The result was that the number of days with no negative potential gradient was reduced. The treatment of the months in which there were not 10 quiet days is shewn in the following list.

	Calendar Days	Other Spells	Total
Feb.	9	1	10
Apr.	6	1	7
Oct.	8	2	10
Nov.	6	2	8
Dec.	8	1	9

Except in the months where other spells were used the non-cyclic change is given explicitly in Table 543, so that anyone who may desire to reproduce the figures as they were before the non-cyclic change was applied can easily do so.

All the inequalities shew a well marked double oscillation with minima in the early morning and early afternoon, maxima in the late morning as well as in the evening. The diurnal inequalities for the whole year shew the higher maximum at 9h., the lower minimum at 4h. This is not the case in every year. The following list gives the annual mean potential gradient for selected quiet days together with the hours of the extremes and the range of the inequality for each year from 1910. The correction of +12 per cent has been applied to the means and ranges of all years from 1910 to 1931.

#### ATMOSPHERIC POLLUTION.

The Owens atmospheric pollution recorder or air filter No.1*is situated in the Clinical House, and the level of the intake is about  $l_2^{\frac{1}{2}}m$ . above that of the adjacent ground. The weight of the pollution is not obtained directly but is deduced from shade numbers 0,1,2, etc., assigned to the deposit left on the filter paper through which the air is drawn. The equivalents of the shade numbers are allotted in accordance with the results of an investigation carried out for the Atmospheric Pollution Committee by Mr.J.G.Clark.t When the normal volume of air, 2 litres, is aspirated (it is drawn through a hole 3.2 mm. in diameter) shade number 1 answers to 0.32 milligrams per cubic metre. The Owens apparatus was designed in the first place for dealing with the air of cities, and the amount of pollution at the Observatory is usually so small that the shade recorded when the 2 litres are aspirated is either 0 or 1.

Preliminary experiments with a spare recorder having justified the assumption that increasing the volume of air would increase the shade number in proportion, an auxiliary tank was brought into use at the beginning of July, 1928. With this tank in operation each spot on the filter paper corresponds with 6.4 litres of air. The unit shade is therefore equivalent to  $0 \cdot \log/m^3$ . When fog prevails the auxiliary tank is put out of action and the unit shade reverts to the value  $0.32 \text{ mg/m}^3$ .

Special attention is paid to the maintenance of consistency in the standard of shades. Each new scale of shades is compared directly with the standard preserved by Dr. Owens. New scales of shades were taken into use on the following dates:-

June 7, 1925; July 1, 1926; (retrospectively) January 1, 1928; August 1, 1930; January 1, 1931; June 1, 1931; and March 1, 1933.

days hours During 1935 the highest estimate of pollution was Jan. 3. 13  $6 \cdot 1 \text{ mg/m}^3$ , this value occurring on December 23rd from Feb. 1 2 18h to 19h. There were 20 days on which the pollution 7 Mar. 3 reached 1.0 mg/m3; the number of hours credited with 3 3 Nov. 1.0 mg/m³. or more being 74. The months in which Dec. 10 49 these days and hours occurred are given in the accompanying table. Year 20 74

Table 544 gives for each month mean hourly values derived from all the days for which complete records were obtained. There were 360 such days in the year. The highest and lowest of these hourly values are underlined.

Table 545 gives diurnal inequalities derived from the date in Table 544 after the application of non-cyclic corrections. The principal reason for computing the diurnal inequalities was to facilitate comparison with the corresponding diurnal variations in barometric pressure and in the potential gradient of atmospheric electricity.

The mean values computed for recent years are given in the following table, together with the means for successive pairs of months. The unit is l mg/m³

^{*}A description of the instrument is given in the "Report of the Advisory Committee for Atmospheric Pollution", 4th Report, 1917-1918, p.20.

The nature of the diurnal variation is most easily recognised in Table There is always a well defined minimum during the night and another 545. in the early afternoon. The first maximum of the day usually occurrs about 9h and the second one follows about 12 hours later. This double oscillation is apparently due to two causes, the variation in human activity in producing pollution and the variation in the wind which disperses it. In 1935 the principal maximum was in the evening from January to May and from October to December; in the forenoon in the remaining months. The principal minimum occurred in the afternoon from May to September; in the early morning in the remaining months. Curves illustrating the diurnal variation of atmospheric pollution will be found in the Annual Reports of the Advisory Committee Atmospheric Pollution and in a paper by Dr. Whipple on the relation between Atmospheric Pollution and Potential Gradient.

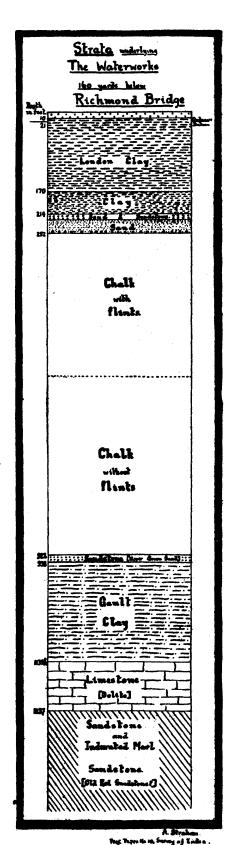

#### SEISMOLOGY.

Notes on Instruments .- The standard seismographs, three Galitzin pendulums with galvanometric registration, were transferred from Eskdalemuir Observatory during the latter part of 1925 and have been in regular operation since the beginning of 1926. Earth movements in the north, east and vertical directions are recorded. The pendulums, which are in the old magnetograph room, are mounted on a massive concrete pillar, separated from the floor. The galvanometers and recording apparatus are accommodated on slate slabs in the old seismograph room, which housed the Milne instrument until it was put out of action on June 17, 1925. To eliminate temperature variation as far as possible, the windows of the pendulum room are provided with triple glass and also shielded by louvred screens from direct sunshine which might fall The annual range of temperature variation is athem morning and evening. bout 10°C. and the mean daily range about 0.2°C. To diminish the sensitivity of the vertical pendulum to temperature changes the steel controlling spring was replaced in May, 1928, by one made of elinvar, an alloy which has a temperature coefficient of elasticity about one-tenth that of steel.* tailed report on the behaviour of the spring has been published in a papert by F.J. Scrase. The difficulties usually associated with the operation of the vertical pendulum have been greatly diminished.

The concrete pillar rests on gravel. The underlying geological strata are shown in the diagram on this page. The diagram is based on the results obtained*in sinking a well near Richmond The Richmond boring terminated at a depth of 440 metres in Old Red Sandstone. Stonebridge Park, 8 km. to the north, a boring was carried downt to a depth of 600 metres, the last 280 metres being in Old Red Sandstone. There is no information as to deeper strata near Rich-It may be noted, however that the sandstone beds dip at about 30° and that a boring at Little Missenden, Bucks, entered rocks at a depth of 370 metres with no evidence of the presence of Old Red Sandstone.

For detailed description of the Galitzin seismograph and for particulars of interpretation of the records, reference may be made to Fürst B Galtizin's "Vorlesungen über Seismometrie" (Leipzig, 1914), or to G.W. Walker's "Modern Seismology" (London, 1913). ††

Timing is controlled by a Synchronome clock (Hope-Jones No.1901) which is rated daily from the Greenwich wireless time-signal relayed by Droitwich. Time breaks are made electro-magnetically every minute and seismometric readings can be determined to the nearest second.

The free periods of the Galvanometers  $(T_1)$ , were determined in November, 1925, and were found to have suffered very little change since the original determinations at Eskdalemuir were made. The lengths of the simple equivalent pendulums (1) are assumed to have remained unaltered.

The Galitzin seismographs were not standardised during 1935, and it has been assumed that the constants had not changed from the values determined in September, 1934. The pendulums were adjusted on January 29th, June 24th and November 1st, 1935 to counter slight tilting of the pillar.

In the following table are summarized the values of the constants. T is the free period of the pendulum,  $\mu$  is a damping coefficient which vanishes when the free movement of the pendulum is just aperiodic, A is the length of the beam of light from the galvanometer mirror to the recording drum (usually about 1100 mm), and k is the

In windy weather the seismographs, especially the horizontal components, are affected by slow oscillations, which are attributed to the tilting of the ground, the movement being conveyed through the foundations of the Observ-On occasions the reading of an earthquake record is rendered very difficult, if not impossible, by these irregular disturbances.

A Wood-Anderson seismograph was also in operation throughout 1935. complete description of this instrument appears in the Bulletin of the Seismological Society of America, XY,1 Mar. 1925. The moving system is very small, that of the Kew instrument consisting of a small copper mass of mensions 25.4mm x4.8 mm x 1.6 mm and weighing 1.5 gm; this mass is attached to the side of a tungsten wire (.025 mm in diameter) stretched at a slight inclination to the vertical. The controlling force is partly due to the torsion of the wire and partly to gravity. The damping is magnetic. Direct optical recording is employed, a small concave mirror of 12 metres focal length being fitted to the moving mass. The instrument is housed in the old magnetograph room beside the Galitzin pendulums, and is oriented to record the N-S component. The approximate constants during 1935 were: - Magnification, 1500; Free period 2 seconds; Damping ratio 20-1.

The Seismological Diary.- Table 546 contains the particulars of the earthquakes recorded at the Observatory. The notation employed is as follows*:-

In the second column of the diary the entries N, E, Z, refer to the records from the north-south, east-west and vertical seismographs respectively.

- P is the normal first phase (longitudinal waves). PKP is a longitudinal wave which has passed through the earth's central core, and PcP one which has been reflected from the core.
- PP, PPP... are longitudinal waves reflected once, twice ... near the earth's surface.

  S is the normal second phase (transverse waves). The waves which penetrate the central core and pass through it as longitudinal vibrations are designated by the symbol SKS.
- PS and PPS are waves which suffer a change or changes from longitudinal to transverse oscillation or vice versa, on reflection near the surface.
  - SS, SSS...are transverse waves reflected once, twice... near the surface.
- For the supplementary reflected waves from deep focus earthquakes the notation used is that introduced by F.J. Scrase, London. Proc. roy. Soc., A. 132, (1931).
  - L indicates long waves (surface waves).
- e means a gradual or indistinct commencement. i is the sudden commencement of a phase. letters are used as prefixes to the phase symbols, but where the character of the phase is not assign-When the commencement of a phase is moderately able the letters are used as independent symbols. clear the prefixes are not used.

^{*}The notation was amended from the beginning of 1933, the most important. change being the adoption of a special letter, K, for the compressional waves This symbol, taken from the Georgetown bulletins, is now through the core. used in the International Seismological Summary. Previously a pulse which started and finished as a transverse wave but passed through the core as a compressional wave was denoted by ScPcS. In the new notation such a pulse is denoted by SKS.

All times entered against the above phases are the times of arrival of the phases at the station. The phases denoted by M are successive prominent maxima occurring during the principal or surface phase.

The period is the duration of a double oscillation (to and fro movement).

The entries under A are the amplitudes, in microns (1µ=0-001 mm.), of the components of the true displacement of the ground from the position of rest. Displacements to the north, east and upwards are regarded as being positive. When successive positive and magnitude the time of occurrence is given for the positive one. When successive positive and negative displacements have the same

The following formulae, due to Galitzin, are employed for computing the times of the maxima and the amplitudes of sinusoidal waves:-

(1) Lag of the displacement shown by the galvanometer after the maximum displacement of the ground

$$= \frac{\mathrm{Tp}}{2\pi} \left[ \left( \frac{\pi}{2} + \operatorname{Arctan} \frac{2u_1}{u_1^2 - 1} \right) + \operatorname{Arctan} \frac{2u(1 + u^2)^{\frac{1}{4}}}{u^2 - 1} \right]$$

each inverse tangent being taken as between 0 and T

(2) Magnification of records

$$= \frac{kA Tp}{\pi C} \frac{1}{(1 + u^2)(1 + u^2) \left\{1 - \mu^2 f(u)\right\} k}$$

 $=\frac{kA\ Tp}{\pi\ \ell} \quad \frac{1}{(1+u^s)(1+u^{\frac{s}{2}})\ \{1-\mu^2f(u)\}\frac{1}{k}}$  in these formulæe T is the period of the earth wave considered, T, T, and  $\mu$  are as defined on p.367.

$$u = \frac{T_D}{T}$$
,  $u_1 = \frac{T_D}{T_1}$  and  $f(u) = \left[\frac{2u}{1+u}\right]^2$ 

 $\Delta$  is the distance in kilometres of the epicentre measured along the arc of a great circle. For earthquakes of normal focal depth located within 10,000 km. of Kew, the distance is generally derived from the interval between P and S by the table, due to Zeissig, given in Klotz's "Seismological Tables" (Publication of the Dominion Observatory, Ottowa, Vol. III, No.2). For greater distances other phases are considered and  $\Delta$  is obtained from the travel curves given by Gutenberg.* In the case of deep focus shocks both  $\Delta$  and the depth of focus are determined from the Brunner diagramt. The azimuth of the epicentre (0° to 360°) is measured from north through east. When an estimation of the azimuth is possible, it is used, together with  $\Delta$ , for provisional determination of the co-ordinates of the epicentre. The co-ordinates given in the Diary have generally been received at a later date; authorities for these determinations are inserted in brackets. Here the letter J.S.A. signify the Jesuit Seismological Association of America, U.S.C.G.S., the United States Coast and Geodetic Survey, and U.R.S.S. the bulletins issued by the United Soviet States.

Brackets enclosing figures or phase symbols indicate that the interpretation is uncertain.

The total number of shocks recorded during the year was 231. The phases being sufficiently well defined, estimates of the epicentral distances were obtained for 72 shocks, whilst in 10 cases the records of the initial impulses were sufficiently sharp to allow of computations of azimuth and so of estimates of the co-ordinates of the epicentres. There were 13 earthquakes which produced a disturbance at the observatory with an amplitude exceeding 0.1mm. in a horizontal component. These earthquakes originated, in the sea of Marmora (January 4th), in the Mediterranean Sea near the coast of Tripoli (April 19th), in Northern Formosa (April 20th), around Quetta (May 30th), in the Pacific Ocean east of Fornosa (September 4th), near Northern Japan (September 11th and October 18th), in new Guinea (September 20th), in the Pacific Ocean off Japan (October 12th), in the Pacific Ocean off Central America (December 14th), in the Solomon Islands (December 15th), south of the Riu-Kiu Islands (December 17th) and in the Indian Ocean off Western Sumatra (December 28th).

For comparison the statistics for all the years in which the Galitzin seismographs have been in operation at Kew Observatory are given:-

Year	Shocks recorded.	Epicentral distances.	Azimuths estimated	Shocks exceeding 0.1 mm.
1926	306	55	•	10
1927	314	76	6	9
1928	339	97	19	18
1929	320	74	6	12
1930	301	56	6	8.
1931	274	53	. 11	16
1932	246	57	8	8
1933	263	71	8	8
1934	269	59	10	9
1935	232	72	10	13

The Brunner Focal Depth-Time-Distance Chart, G.T. Brunner and J.B. Macelwane, New York, 1935.

Microseisms. The routine tabulations of microseisms recorded at Kew, and previously at Eskdalemuir, have hitherto been taken from the north-south component for each day at Oh, 6h, 12h and 18h. The results obtained from a comparison of the microseisms recorded by the three components during a complete year (1932) have shown* that the vertical is more reliable than either of the horizontal components for such tabulations. The advantages of the vertical component are:-

- (a) The amplitude recorded does not depend upon the direction of travel of the waves.
- (b) The effects of the local geological structure are smaller.
- (c) For oscillations with the period of microseisms the vertical Galitzin seismograph has, with the tuning adopted at Kew, the higher magnification.
- (d) Freedom from wind disturbance.

The vertical component has therefore been adopted from the beginning of 1935. The results obtained for 1932 shewed that, within the accuracy of the measurements, the annual means of amplitude and period were equal for the three components.

The hours of tabulation are the same as for the north-south component in earlier years. The group of waves of greatest amplitude occurring in the 30 minutes centring at the hour in question is selected, and the amplitude tabulated is the mean obtained from the three largest complete waves in that group. The period is obtained from a measurement made on the same group. The total time, to the nearest second, for a number of complete consecutive waves is measured, the number of waves being chosen so that the time is between 23 and 30 seconds. The period is then derived from the following division table:-

Number of		T	ime inter	val in se	conds.	1 .									
Waves.	<b>3</b> 0	. 29	28	27	26	25	24	23							
3	10-0	9-7	9-3	9•0	8-7	8-3	8•0	7-7							
4	7•5	7-3	7-0	6•7	6.5	6-3	6•0	5.7							
5	6•0	5•8	5•6	5-4	5-2	5-0	4.8	4.6							
6	5•0	4.8	4.7	4.5	4.3	4.2	4.0	3-8							
7	4.3	4-1	4-0	3-9	3.7	3-6	3-4	3-3							
8	3.7	3-6	3-5	3-4	3-3	3.1	3-0	2.9							
9	3•3	3-2	3-1	3-0	2.9	2.8	2.7	2.6							
10	3-0	2-9	2-8	2-7	2-6	2.5	2.4	2.3							
11	2.7	2.6	2.5	2.5	2.4	2.3	2.2	2.1							
12	2-5	2-4	2-3	2-3	2.2	2.1	2.0	1.9							

On the occasions of failure of the Z record, gaps in the tabulations have been filled in by interpolation or from measurements of the microseisms recorded by the horizontal seismographs. By use of the data of 1932 (Geo-physical Memoir No.66) it was found that there was a linear relation between the ratio of horizontal to vertical amplitudes and the period of the oscillations, the ratio varying from 1.2 for microseisms of period  $4\frac{1}{2}$  sec. to 0.85 for those of period 9 sec. Allowance is accordingly made for the difference between the amplitudes recorded by the horizontal and vertical compo-

nents. Values obtained by interpolation or from the horizontal seismograms are bracketed in the tables.

The mean values of amplitude and period, together with the maximum amplitudes, for each month of 1935 are given below:-

Kew Observatory.	Microseisms of	Vertical	Component.	1935.
TOM ODDETACOTA	WIGIODGIDED OF	for or our	composion o.	1000

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept	Oct.	Nov.	Dec.	Year
Mean Period. (sec.).	6-5	6•3	6-3	5-2	5.1	4.9	5-0	4.8	5-2	6-1	6-5	6-1	5•7
Mean Amplitude (μ)	1.7	2-6	1-3	0-7	0-2	0-2	0.2	0-2	0-6	1-4	1.8	1-9	1.1
Maximum Amplitude ( $\mu$ )	(12-1)	6-3	4.8	3-3	0-7	1.1	0-8	1.8	3-6	10-6	8-8	5-1	(12-1)
Day and hour of Maximum Amplitude	25;18	21;12	1;0	11;12	15;0	(8;0) (24;12)	(16;6 (16;18)	23;12	19;18	19;6	30;12	1;0 J	an 25;18

For comparison, the following table gives the monthly means of amplitude and period of the N-S component microseisms at Kew from 1926 to 1934.

Kew Observatory. Microseisms of North-South Component. 1926-34.

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept	Oct.	Nov.	Dec.	Year
Mean period (sec).	6•5	6-1	5-9	5•4	4•9	4.7	4-4	4-6	<b>5•</b> 0	5•4	6-0	6•4	5•5
Mean amplitude $(\mu)$ .	2-3	1.6	1-4	0-9	0•5	0-4	0•3	0-5	0•6	1.1	1-6	2-0	1.1

The means of amplitude and period for the several hours are given in the following table. The values given are for the vertical component during 1935, and the average values for the N-S component from 1926 to 1934.

	Hour	(G.M.T.)	Oh.	6h.	12h.	18h.
z.	(1935)	Amplitude $(\mu)$ . Period (sec).	1-09 5-65	1•05 5•66	1.07 5.64	1.07 5.67
N-S	(1926-34)	Amplitude $(\mu)$ . Period (sec).	1·10 5·46	1.09 5.45	1.06 5.42	1.08 5.45

These figures indicate that there is no regular diurnal variation in the amplitude or period of the microseisms recorded by the Z and N-S components at Kew Observatory.†
